

World Fertility Patterns 2009

www.unpopulation.org

Introduction: The last decades of the twentieth century witnessed a major transformation in world fertility: total fertility fell from an average of 4.7 children per woman in 1970-1975 to 2.6 children per woman in 2005-2010. This change was driven mostly by developing countries (excluding the least developed countries), whose fertility dropped by more than half (from 5.6 to 2.5 children per woman). The decline was less marked among the least developed countries where fertility remains high, with fertility having declined from 6.3 children per woman in 1970-1975 to 4.4 in 2005-2010. This chart presents some of the data available to assess the change in fertility taking place in countries of the world. For the 224 countries or areas for which data are available, it displays unadjusted data on total fertility, age-specific fertility and the mean age at childbearing for two points in time: the first as close as possible to 1970 and the second showing the latest available data. Data on total fertility for the world as a whole, the development groups and major areas are estimates referring to 1970-1975 and 2005-2010 derived from the 2008 Revision of World Population Prospects.¹ The chart thus presents world and regional estimates of fertility change together with the actual data underlying those estimates.

Data sources: The data at the country level were derived from various sources. For developed countries and some developing countries, measures of fertility were derived from information on births by age of mother obtained from civil registration systems achieving a level of coverage of at least 90 per cent. For developing countries whose civil registration systems achieved coverage of births lower than 90 per cent

or where there were no data from a civil registration system, fertility measures were obtained from surveys or censuses. Data in the chart are a subset of the fertility data contained in *World Fertility Data 2008*.²

Data coverage: Among the countries or areas considered, 211 countries or areas have data referring to 2000 or later and they accounted for 98 per cent of the world population in 2008. For 12 other countries or areas, the most recent data presented refer to years ranging from 1994 to 1999. Among those 12 countries, only one is a developed country (Channel Islands) and five are least developed countries. Only one country in the chart (Saint Pierre and Miquelon) has no data available since 1994. For the first period, with data referring to dates as close as possible to 1970, 188 countries had data for the period 1966-1975, accounting for 94 per cent of the world population in 2008. For 117 countries data refer exactly to 1970. For Mali and the Niger the data refer to 1960, to Benin to 1961, for Cambodia to 1962 and for Chad to 1963. For a further 28 countries, accounting for 5 per cent of the world population in 2008, the earliest data available refer to the period between 1976 and 1994. Three countries in the chart have no data available for the period around 1970. Six countries or areas—Falkland Islands (Malvinas), Holy See, Isle of Man, Monaco, Pitcairn and Western Sahara—have no data on fertility for either period and are not included in the chart.

Period covered: In many developed countries, fertility began declining as early as the nineteenth century and most recorded low levels of ferti-

lity long before 1950. Indeed, fertility rose in many developed countries during parts of the period 1945-1965, as it recovered from the low levels reached during the Second World War. By the 1970s, however, fertility in developed countries was falling again. In the developing world, fertility levels remained high until the 1960s and began falling in most countries of Latin America and the Caribbean and some in Asia during the late 1960s. By the 1970s and early 1980s declining fertility was common in most developing countries outside of sub-Saharan Africa, where fertility started declining later, mostly in the late 1980s or the 1990s. In the data presented the periods spanned by the earliest and latest data sets for each country or area vary considerably. Among the 224 countries or areas covered, 172 have data spanning intervals ranging from 30 to 39 years. For a further 34 countries, the data span intervals ranging from 20 to 29 years, and in another 10, the intervals span less than 20 years. For four countries the interval is longer than 39 years. In addition, four countries or areas, all with fewer than 100,000 inhabitants in 2008, have data for only one period.

Total fertility: Focusing on the 220 countries or areas with two observations, total fertility for the most recent year available varies between 1.0 child per woman in Macao, Special Administrative Region of China, in 2006 and 7.4 children per woman in Guinea-Bissau in 2000. Among the 45 developed countries with more than 100,000 inhabitants in 2008, total fertility varies between 1.2 and 2.0 children per woman, with only three countries having fertility levels outside that range: Iceland, New Zealand and the United States of America with close to 2.1 children per

woman in 2006. In 21 developed countries, fertility declined by between 0.2 and 0.4 children per decade since around 1970. The fastest decline among developed countries occurred in Albania, at 1.1 children per decade. Among the 150 developing countries with more than 100,000 inhabitants in 2008, all but 31 experienced a reduction of fertility averaging 0.4 children per decade or more, according to the unadjusted data presented in this chart. However, in seven least developed countries with current fertility levels above 6.0 children per woman, fertility has hardly changed and unadjusted data show no reduction or a reduction of less than 0.1 children per decade. In contrast, 46 developing countries achieved reductions of fertility averaging one child per decade or more. As a result of rapid fertility declines, total fertility in 72 of the developing countries considered was at or below 3.0 children per woman at the most recent date considered. Yet 31 of the 49 least developed countries still exhibit a total fertility equal to or higher than 5.0 children per woman for the most recent date available.

The mean age at childbearing: The process of fertility decline is associated with changes in the age distribution of childbearing. Usually fertility starts declining when women limit the size of their families by stopping childbearing earlier than their mothers did. Hence, fertility declines at older ages, making the mean age at childbearing decrease. When fertility is already moderately low, a different process may be observed: women postpone childbearing, thus reducing fertility at younger ages and increasing the mean age at childbearing. Among the 45 developed countries with more than 100,000 inhabitants in 2008, 12 countries had

a mean age at childbearing surpassing 30 years. The oldest mothers in developed countries are in Ireland, whose mean age at childbearing was 31.1 years in 2006. Among developing countries, Bangladesh has the lowest mean age at childbearing, at 25.1 years in 2005, whereas the Libyan Arab Jamahiriya has the highest at 36.8 years in 2002.

Adolescent birth rate: Fertility levels among women aged 15-19 are an important indicator of the status of women, since women who bear children early in life often forgo the opportunity to study or find employment outside the home. Reducing the adolescent birth rate is also one of the objectives of the Millennium Development Goals. Among developed countries, the adolescent birth rate is generally low and varies between 4 and 41 births per 1,000 women aged 15-19. Only four developed countries have an adolescent birth rate above 30: Bulgaria, Romania, Ukraine and the United States of America, which has the highest value of 41 births per 1,000 women aged 15-19. In developing countries the range of variation of the adolescent birth rate is considerably larger: from below 5 to over 190 births per 1,000 women aged 15-19. The highest rates are recorded in Chad, Mali and the Niger. The adolescent birth rate is particularly high (above 90 births per 1,000 women aged 15-19) in at least 50 developing countries, 31 of which are least developed countries. In 24 developing countries, the adolescent birth rate is lower than 20 births per 1,000 women aged 15-19.
