The views expressed in the paper do not imply the expression of any opinion on the part of the United Nations Secretariat.

The designations employed and the presentation of material in this paper do not imply the expression of any opinion whatsoever on the part of the United Nations Secretariat concerning the legal status of any country, territory, city or area or of its authorities, or concerning the delimitation of its frontiers or boundaries.

The term "country" as used in this paper also refers, as appropriate, to territories or areas.
This publication has been issued without formal editing.

The Population Division of the Department of Economic and Social Affairs of the United Nations Secretariat is responsible for providing the international community with up-to-date and scientifically objective information on population and development. The Population Division provides guidance on population and development issues to the United Nations General Assembly, the Economic and Social Council and the Commission on Population and Development and undertakes regular studies on population estimates and projections, fertility, mortality, migration, reproductive health, population policies and population and development interrelationships.

The purpose of the Technical Paper series is to publish substantive and methodological research on population issues carried out by experts within and outside the United Nations system. The series promotes scientific understanding of population issues among Governments, national and international organizations, research institutions and individuals engaged in social and economic planning, research and training.

This paper presents new estimates and projections of the number of women of reproductive age ( 15 to 49 years) who are married or in a union for the period 1970 to 2030. The projection approach assumes changes in age-specific proportions married or in a union based on two variants of a model pattern towards which countries would converge: 1) prevalence of marriage or cohabitation at young ages is low and (2) prevalence of marriage or cohabitation at young ages remains relatively high even at low fertility levels. The estimates and projections of the number of women of reproductive age ( 15 to 49 years) who are married or in a union were prepared for individual countries on an age-specific basis (for five-year age groups 15-19 to 45-49), which accounts for: 1) substantial changes in age structure in the reproductive ages that have occurred from 1970 to 2010 and the projected changes in age structures during the projection period to 2030; and 2) observed and projected trends in the age-specific proportions married or in a union. The results are useful for estimating the number of contraceptive users and women with unmet need for family planning and are necessary for calculating regional and world aggregates of family planning indicators. Kyaw Kyaw Lay, of the Population Division, provided assistance in implementing the models and computing regional aggregates. Preparation of this report benefited from comments received from Ann Biddlecom, of the Population Division.

The Technical Paper series as well as other population information may be accessed on the Population Division's website at www.unpopulation.org. # NATIONAL, REGIONAL AND GLOBAL ESTIMATES AND PROJECTIONS OF THE NUMBER OF WOMEN AGED 15 TO 49 WHO ARE MARRIED OR IN A UNION, 1970-2030 

Vladimíra Kantorová*

## INTRODUCTION

The objective of this technical paper is to provide estimates and projections of the number of married or in-union women for the period 1970 to 2030 at the national, regional and global levels. These estimates and projections are relevant for 1 ) describing family planning trends at the regional and global level (United Nations, 2004, 2011a, 2012); 2) informing projections of family planning indicators (Alkema et al., 2013; London Summit on Family Planning, 2012); 3) understanding the economic, health and population impacts of investments in family planning (Singh and Darroch, 2012; Stover et al., 2010); and 4) informing the proximate determinants framework for analysis of fertility levels and trends (Bongaarts, 1978).

Contraceptive prevalence and unmet need for family planning are most often reported for the base population of married or in-union women of reproductive age (MWRA). In order to estimate the number of contraceptive users or users of particular methods and the number of women with unmet need for family planning, the prevalence rates must be multiplied by the total number of MWRA. To these base numbers for women who are married or in a consensual union, the number of contraceptive users and those who need family planning among unmarried women are added to obtain the number of all contraceptive users and the number of all women with an unmet need for family planning (see Singh and Darroch, 2012). Estimates and projections of MWRA are also needed to calculate contraceptive prevalence and unmet need for family planning for global, regional or other aggregate groups and for country-specific annual estimates and projections from models (see Alkema et al., 2013; United Nations, 2012).

Improved estimates and projections of the proportion and number of women who are currently married or in-union are also important for models of fertility that use the proximate determinants framework (which assumes that most births are within marriage or cohabiting unions). In some regions of the world, particularly in Asia, declines in fertility rates among adolescent and young women have been related to rapid declines in the proportion of women in those age groups who are married or in a union. As a result, the postponement of marriage or union formation has had a large impact on total fertility in those regions. In countries where an increasing proportion of births occur outside of marriage, many of these non-marital births are to women who are living in consensual unions. In some regions, though, the relationship between union status and childbearing is not as strong.

The paper first reviews definitions used in reporting marital status and union status data and describes major sources of data and their availability. The next part of the paper describes the methodology used to derive estimates and projections, building on an approach used in previous sets of projections of married women of reproductive age (United Nations, 1996; United Nations, 2004). The trends in the number of MWRA in the world and by regions from 1970 to 2030 are then presented, including comparisons with a "no change" scenario.

[^0]
## DATA

## 1. Definitions

For the purpose of this study, women who are currently married or in a union are either 1) women who have been married and are not divorced, widowed or separated or 2 ) women who are living in a cohabiting union. ${ }^{1}$ The question usually asked in censuses and surveys is on the marital status or union status of an individual. The definitions of marital status and union status of individuals differ by the source of data, country and time period. For example, in the United Nations principles and recommendations for census taking, only registered partnerships and consensual unions that are legal and binding under law should be reported (United Nations, 2008). ${ }^{2}$ Furthermore, there is considerable variation among the definitions and terminology used in surveys. The Demographic and Health Surveys, one of the major sources of data on marital and union status, ask individuals whether they are married or 'living together' with a partner; ${ }^{3}$ however, in countries with low prevalence of cohabiting unions, the survey question is normally limited only to marriage.

In the Population Division's database on marriage and in the publicly-available data set World Marriage Data 2012 (United Nations, 2013b), consensual unions are included as a separate category whenever survey and census data report on persons living in consensual unions. For the current study, to the extent possible, the category of women in a union includes women living with their partner in the same household. Therefore, categories such as "having boyfriend" or "living-apart-together (LATs)" that are reported in some surveys were not included in the category of women who are married or in a union. An exception to this rule is "visiting partnership", common in the Caribbean region, which is also included in the category of women who are married or in a union.

## 2. Data sources and data availability

For the calculation of the number of married or in-union women for the period 1970 to 2030, two sets of input data are used: 1) estimates and projections of the number of women of reproductive age by five-year age groups from World Population Prospects: The 2012 Revision (United Nations, 2013c) and 2 ) the age-specific proportions of married or in-union women. The latter data are compiled and assessed

[^1]in terms of comparability and quality of data by the Population Division in the database on marriage. The most recent publication from this database is World Marriage Data 2012 (United Nations, 2013b), which provides a comparable and up-to-date set of national data on the marital status of the population by age and sex for 221 countries and territories of the world for five reference dates: 1970, 1985, 1995, 2005 and the most recent data available.

Table 1 shows the availability of marital status data in countries and territories based on the collection of data in World Marriage Data 2012. Regarding the availability of a historical trend series, 113 countries and territories - just over half with any data on marital status-have five data points available for the period around 1970 to 2011, and more than two-thirds of European countries compared to only one-fifth of the countries in Oceania have at least five data points in the past four decades. Recent data are not available for all countries or territories: 32 countries and territories do not have any data for the period from 2000 onwards.

TABLE 1. COUNTRIES AND TERRITORIES WITH DATA ON AGE-SPECIFIC PROPORTIONS OF MARRIED OR IN-UNION WOMEN FROM OFFICIALLY PUBLISHED NATIONAL SOURCES, BY MAJOR AREA, 1970-2011

| Major area | Number of countries with: |  |  | Proportion of countries with any data (per cent) |  |
| :---: | :---: | :---: | :---: | :---: | :---: |

Source: World Marriage Data 2012 (United Nations, 2013b)
Data used in this study for 221 countries and territories ${ }^{4}$ were selected from World Marriage Data 2012 on the basis of comparability over time and across space. Two data points per country are used: one for the period around 1970 and one for the recent period from 2000 to 2011. Some exceptions were made, particularly if comparability of data from specific data sources was thought to be a problem. For example, survey data including cohabiting unions were used instead of census data based only on formal marital status. Moreover, additional data not included in World Marriage Data 2012 were used when the most recent census or survey data became available from January to April 2013. For 16 countries and territories ${ }^{5}$ only one suitable data point was available over the whole period and thus estimates and projections are based only on this data point (see detailed description in the section on methodology). For 10 countries and territories ${ }^{6}$ there are no data available on marital status. While

[^2]estimates and projections for these countries and territories are not produced on a country-specific basis, their population is included in regional and global estimates.

Population estimates and projection of the age-specific number of women are available from the World Population Prospects: The 2012 Revision for 233 countries and territories comprising the total population of the world.

For most countries and territories, marital status or union status data are obtained through censuses, population registers and surveys. Data on marital status from censuses and national estimates are collected, published and maintained by the Statistics Division of the Department of Economic Affairs of the United Nations Secretariat (UNSD) in its Demographic Yearbook data collections (United Nations, 2013a). In addition, the Population Division compiles information from censuses and national estimates not available through the Demographic Yearbook data collections and from various demographic surveys. The sources of data selected for the study vary by time period and geographical area (table 2). Of 214 countries and territories with data for the earlier reference year, the majority of data points are from censuses (191 data points) and only a small number of data points (23 data points) are from surveys and national estimates. The sources of data for the later reference year are quite different: half of the data points are from surveys that provide more timely data (since censuses are generally conducted every 10 years and tabulations were not available for this analysis for many censuses from the 2010 round). In many cases surveys offer more information on different types of unions.

TABLE 2. COUNTRIES AND TERRITORIES BY THE TYPE OF DATA SOURCE, EARLIER AND LATER PERIOD, BY MAJOR AREA

| Major area | Earlier year |  |  |  | Later year |  |  |  |

Note: Earlier period is around 1970; latter period is from 2000 to 2011.

## 3. Data on consensual unions

Not all selected data points contain information on the prevalence of cohabiting unions (table 3). In the earlier period, less than one-fourth of data points provided information on cohabiting unions, while in the recent period more than half of data points provide such information. In some countries without data on cohabiting unions, there are cultural and social barriers towards unmarried cohabitating unions (e.g., countries in Southern Asia or Northern Africa) and assumptions that such unions constitute a minimal proportion of all unions may be appropriate. There are a number of data points where the married category presumably included both formal and informal marriages (as was the case in many censuses in sub-Saharan Africa in the 1970 and 1980 census rounds), thus there was no need for additional assumptions on the prevalence of cohabiting unions.

Alternative information on consensual unions was used for 41 countries and territories in the earlier period and 40 countries and territories in the recent period. Alternative sources of information were based on: 1) neighboring countries with available data (e.g., information on the prevalence of cohabiting unions in the Bahamas was used for a number of countries in the Caribbean); 2) a regional estimate calculated from a number of data points available in the respective region (e.g., the estimate for Western Europe in the 1970s); 3) information from a survey or census that took place in the country in the same time period (e.g., an estimate of the prevalence of cohabiting unions from the 2003-2004 Generations and Gender Survey in Italy complemented the national estimate of the proportion of married); 4) tabulation of census microdata available from the Integrated Public Use Microdata Series (IPUMS) (Minnesota Population Center, 2013) (e.g., Austria, Spain and Portugal); and 5) back-projections based on trends in the prevalence of consensual unions in a country (e.g., Australia and Canada). The majority of the alternative information on prevalence of cohabiting unions was used for countries in Europe and Latin America and the Caribbean. For countries in Africa and Asia, surveys and censuses either provided the information needed or the prevalence of cohabiting unions was considered to be low.

TABLE 3. COUNTRIES AND TERRITORIES WITH DATA ON AGE-SPECIFIC PROPORTIONS OF WOMEN IN COHABITING UNIONS, EARLIER AND LATER PERIOD, BY MAJOR AREA

| Major area | Earlier year |  |  | Later year |  |  |

## METHODOLOGY

The methodology used builds upon the approach adopted in two previous sets of projections of married or in-union women of reproductive age (MWRA) (United Nations, 1996, 2004). In the first step, estimates of age-specific proportions of married or in-union women (ASP-MWRA) are created for the period from 1970 to the most recent data point available. In the second step, beginning from the most recent data point, the projected ASP-MWRA are based on the past national trends combined with the trends towards the model patterns of ASP-MWRA.

MWRA estimates and projections were prepared for individual countries and territories on an age-specific basis (for five-year age groups 15-19 to 45-49), which accounts for: 1 ) substantial changes in age structure in the reproductive ages that have occurred from 1970 to 2010 and the projected changes in age structures during the projection period (2010-2030); and 2) observed and projected trends in the ASPMWRA.

The estimates and projections for particular countries and territories depend upon the extent of data availability of age-specific proportions married or in-union (ASP-MWRA) for one time point (case I) or for two time points (case II). ASP-MWRA data were available for two time points for 205 countries and territories, covering 99 per cent of the population of women of reproductive age in the world in 2010. ASP-MWRA data for one time point were available for 16 countries and territories.

## 1. Method for estimating the age-specific proportions of married or in-union women

Case I. Countries with data at one time point only:
ASP-MWRA are held constant between 1970 and the year of the data point available.
Case II. Countries with two time points:
ASP-MWRA are held constant between 1970 and the year of the earlier data point available. Linear estimates between ASP-MWRA of the earlier and later data points are calculated.

## 2. Method for projecting the age-specific proportions of married or in-union women

Case I. Countries with data at one time point only:
The projection of ASP-MWRA assumes that the proportions converge to the model pattern, beginning from the year of observed ASP-MWRA.

Let:
$t_{0}=$ year of observed ASP-MWRA
$t_{T}=$ year model pattern reached ( $=2040$ )
$p_{t}=$ ASP-MWRA at time $t$
$p_{T}=$ ASP-MWRA in the model population
For $t_{0}<t<t_{T}$, the proportion of the interval [ $\mathrm{t}_{0,2040}$ ] that has elapsed at time $t$ is:
$\tau=\left(t-t_{0}\right) /\left(t_{T}-t_{0}\right)$
Assume that the country ASP-MWRA approach the model pattern as follows:

$$
\begin{equation*}
\operatorname{logit}\left(p_{t}^{\prime}\right)=\operatorname{logit}\left(p_{0}\right)+\tau\left(\operatorname{logit}\left(p_{T}\right)-\operatorname{logit}\left(p_{0}\right)\right) \tag{1}
\end{equation*}
$$

where $\operatorname{logit}(p)=\ln (p /(1-p))$, by definition, and

$$
p=\exp (\operatorname{logit}(p)) /(1+\exp (\operatorname{logit}(p)))
$$

Case II. Countries with two time points:
The projected ASP-MWRA are a weighted average of two preliminary projections: (a) assuming the observed trend continues into the indefinite future; and (b) assuming that the proportions converge to the model pattern, beginning from the most recently observed ASP-MWRA, according to the rule in Case I above.

Let:
$t_{e}=$ year of the earlier data point available for ASP-MWRA
$t_{r}=$ year of the more recent data point available for ASP-MWRA
$p_{e}=$ age-specific proportion married or in-union at the earlier data point
$p_{r}=$ age-specific proportion married or in-union at the more recent data point
Projected ASP-MWRA at time $t, p_{t}$, is calculated as:

$$
\begin{equation*}
\operatorname{logit}\left(p_{t}\right)=\tau\left(\operatorname{logit}\left(p_{t}^{\prime}\right)\right)+(1-\tau) \operatorname{logit}\left(p_{t}^{\prime \prime}\right) \tag{2}
\end{equation*}
$$

where $p_{t}^{\prime}$ is the projected ASP-MWRA at time $t$ as in (1) above, substituting $p_{r}$ in place of $p_{0}$, and $\tau=\left(t-t_{r}\right) /\left(t_{T}-t_{r}\right)$. Furthermore $p^{\prime \prime}{ }_{t}$ is the projected ASP-MWRA at time $t$, assuming the past trend was to continue into the future under the following rule:

$$
\begin{equation*}
\operatorname{logit}\left(p^{\prime \prime}{ }_{t}\right)=\operatorname{logit}\left(p_{r}\right)+\frac{t-t_{r}}{t_{r}-t_{e}}\left(\operatorname{logit}\left(p_{r}\right)-\operatorname{logit}\left(p_{e}\right)\right) \tag{3}
\end{equation*}
$$

## 3. Constant scenario

Results of the projections for years 2020 and 2030 are compared with a constant variant, in which it was assumed there was no change in age-specific proportions of married or in-union (ASP-MWRA) after 2010. ASP-MWRA of 2010 have been applied to the numbers of women by age groups projected for years 2020 and 2030. Similar assumptions of the constant variant were used in other studies, such as the short-term projection to 2012 of the number of contraceptive users and women with unmet need for family planning (Singh and Darroch, 2013).

## 4. Assumptions on the model patterns for year 2040

Two model patterns of age-specific proportions married or in-union (ASP-MWRA) towards which all countries would eventually converge were created. These model patterns provide a simple mechanism for moderating the projections of ASP-MWRA in order to avoid the extreme results that might, in some countries, result from projecting the future situation from rapid changes in the past and provide a basis for projecting proportions married or in-union in 16 countries where direct information about trends was unavailable.

The projections assume that the model patterns would not be reached until 2040, 29 years after the last observed data in 2011. An examination of ASP-MWRA in countries in an advanced state of demographic transition showed the existence of two patterns: 1) where the proportion of adolescent and young adult women (15-24 years old) who are married or in a union is very low; and 2 ) where the proportion of adolescent and young adult women who are formally married is low but where the proportion who are cohabiting is fairly high. Thus, there are two variants of the model proportions to be reached in year 2040. The Model I pattern is based on data from a number of countries ${ }^{7}$ with late union formation. The Model I pattern is used in projections for the countries of Eastern Asia, Northern Africa, Southern Europe and Western Asia. For all other countries, Model II—derived from data for a number of

[^3]countries with earlier union formation patterns—was used. ${ }^{8}$ Table 4 shows the model proportions to be reached in 2040 for the two model patterns. The differences between the two model patterns are most evident in the youngest age groups: while 2 per cent of women aged 15 to 19,14 per cent of women aged 20 to 24 and 42 per cent of women aged 25 to 29 are married or in-union in Model I, the proportions are 5 per cent, 28 per cent and 58 per cent, respectively, in Model II.

TABLE 4: MODEL PROPORTIONS OF WOMEN WHO ARE MARRIED OR IN-UNION TO BE REACHED IN 2040

|  | Proportion of women <br> who are married <br> or in-union |  |
| :---: | :---: | :---: |
| Age groups | Model I | Model II |
| $15-19$ | 2 | 5 |
| $20-24$ | 14 | 28 |
| $25-29$ | 42 | 58 |
| $30-34$ | 66 | 70 |
| $35-39$ | 76 | 76 |
| $40-44$ | 80 | 75 |
| $45-49$ | 80 | 75 |

The projection procedures ensure that the near-term projection results are determined primarily by the trends observed in each country. The choice of alternative models has little effect until the later years of the projection period.

## 5. Examples and discussion of the method

The estimation and projection method is illustrated on two quite different examples of women aged 20 to 24 in Afghanistan and Austria (figures 1a and 1b, respectively). Estimates and projections for Afghanistan are based on data on the proportion married by age group from the 1973 census and the 2010 Mortality Survey. For Austria, the two data points selected are the 1971 census and the 2008-2009 Generations and Gender Survey, and both sources also include information on age-specific prevalence of consensual unions. Afghanistan and Austria are in the group of Model II countries, for which the model proportion of married and in-union women to be reached in 2040 is 28 per cent. For the near-term future, the projections for each country are in line with recent trends and only gradually turn towards the model pattern for 2040.

[^4]Figure 1a: Estimates and projections of the proportion of women aged 20 to 24 who are married or in a union (per cent), Afghanistan, 1970-2030

Figure 1b: Estimates and projections of the proportion of women aged 20 to $\mathbf{2 4}$ who are married or in a union (per cent), Austria, 1970-2030

There are several limitations to the current method. First, the method uses only two data points per country and the past trends are estimated assuming a linear trend over time. Thus, the different pace of change over time in the proportions of women married or in-union cannot be analyzed. Second, two model patterns used for year 2040 were established after an examination of countries at an advanced state of demographic transition. It is, however, possible that some regions will stay at a pattern with early marriage and union formation even after the demographic transition is completed. In the current situation, all countries with early marriage patterns have been experiencing substantial declines in the proportion of married or in-union women at younger ages, thus an additional model pattern was not considered.

## RESULTS

In the past four decades, the estimated number of women of reproductive age who are married or in a union nearly doubled from 590 million in 1970 to 1.16 billion in 2010 (figure 2; table A.2. in the appendix). The projection results indicate a further increase to 1.22 billion by 2020, followed by a slight decline to 1.21 billion in 2030. Still, the sub-regions of Africa will experience fast growth. Between 2010 and 2030, the projected increase in the number of women of reproductive age who are married or in a union is 62 per cent in Eastern Africa, 60 per cent in Middle Africa and 44 per cent in Western Africa (table A.2. in the appendix).

Figure 2: Number of married or in-union women aged 15 to 49, 1970-2030, world (billions)

Projections of the proportions married or in-union, on an age-specific basis, are based on the past national trends and convergence towards the model patterns of age-specific proportions of women who are married or in-union. Since the age at marriage or at union formation has been rising in many countries, the proportions of married or in-union women in younger age groups (15-19, 20-24) declined from 1970 to 2010 in all regions, and similar declines are projected also for the future (figure 3). As of 2010, more than one-fifth of women aged 15 to 19 years were married or in-union in Eastern Africa, Middle Africa and Western Africa. In South-Central Asia, the proportion of 15 to 19 year old women who were married or in a union declined dramatically from 52 per cent in 1970 to 19 per cent in 2010. For all regions with a high prevalence of marriage among adolescents ( 15 to 19 years old), the projections are expected to decline further to levels around or below 10 per cent by 2030 .

Figure 3: Proportion of married or in-union women in age groups 15-19 and 20-24, 1970-2030, by region (per cent)

Figure 3: (continued)

The standard reference group for measurement of family planning indicators has traditionally been women who are married or in a union. However, unmarried women who are sexually active also need access to pregnancy prevention information and services. The results of this study emphasize the importance of understanding the family planning needs of the growing number of women who are not married or in a union. Among all women of reproductive age in the world, 31 per cent were not married or in a union in 1970, increasing to 36 per cent in 2010 and projected to increase to 40 per cent in 2030. Among young women, the proportion who are not married or in a union is projected to increase from 87 per cent in 2010 to 93 per cent in 2030 among 15 to 19 year olds and from 53 per cent in 2010 to 66 per cent in 2030 among 20 to 24 year olds.

The comparison of the projections and the constant variant gives a sense of the impact of the model approach used. The results of the constant variant and its comparison to the projections for years 2020 and 2030 are presented in annex table A. 3 for all major areas and regions. With an assumption of no change in the age-specific proportions of married or in-union after year 2010, the estimated number of MWRA in the world would be higher by 5 per cent in 2020 and by 12 per cent in 2030. The largest difference between the constant variant and the projection was calculated for Western Africa, where the number of married or in-union women would be 22 per cent larger compared with the projections in 2030. The differences between the constant variant and the projections are also large in Eastern Africa and Middle Africa, at 17 per cent in 2030. In terms of population numbers, the difference between the constant variant and projections in Africa and Asia contributed the most to the difference at the world level (figure 4).

Figure 4: Number of married or in-union women of reproductive age, projections and constant variant assuming age-specific proportion of married or in a union as of 2010, by major area, 2010, 2020 and 2030 (thousands)

## CONCLUSIONS

This technical report described the methodology for estimating and projecting the number and proportion of married or in-union women of reproductive age. The results presented in the report are based on the estimates and projections of the age-specific female population from World Population Prospects: The 2012 Revision (United Nations, 2013c) and on the marital status data from World Marriage Data 2012 (United Nations, 2013b) complemented by estimates of the prevalence of cohabiting unions for countries where data on cohabiting unions were not available from the source of data presented in World Marriage Data 2012. For further applications, the national, regional and global estimates and projections for the period from 1970 to 2030 on an annual basis are provided in Excel format at the Population Division website (www.unpopulation.org).

The earlier version of the estimates and projections using World Population Prospects: The 2010 Revision (United Nations, 2011b) was used in calculations of the regional and global indicators of contraceptive use and unmet need for family planning published in the Millennium Development Goals Report 2013 (United Nations, 2013d).

[^0]:    * Fertility and Family Planning Section, Population Division/DESA United Nations

[^1]:    ${ }^{1}$ In this paper, there is no distinction made with respect to the terms used in different publications, such as informal unions, consensual unions, unmarried unions, or "living together", which are used in the text when referring to the sources of data using these terms. To the extent possible, the category of women in a union includes women living with their partner in the same household and who are not married according to the marriage laws or customs of a country.
    ${ }^{2}$ The categories of marital status, that is the personal status of each individual in relation to the marriage laws or customs of a country, identified in the Principles and Recommendations for Population and Housing Censuses, Revision 2 are: (1) single (never married); (2) married; (3) widowed and not remarried; (4) divorced and not remarried; and (5) married but separated. Furthermore, the recommendations and principles state in paragraph 2.146 that customary unions, such as registered partnerships and consensual unions, should be listed separately when they are legal and binding under law (United Nations, 2008). Reported census data on consensual unions for the Demographic Yearbook data collections (United Nations, 2013a), however, do not necessarily conform to this recommendation.
    ${ }^{3}$ In the country reports of the Demographic and Health Surveys, the term 'married' generally refers to legal or formal marriage, while the term 'living together' designates an informal union in which a man and a woman live together but a formal civil or religious ceremony has not taken place.

[^2]:    ${ }^{4}$ The estimates and projections for the Netherlands Antilles in this report cover populations of the Caribbean Netherlands, Curaçao and Sint Maarten (Dutch part).
    ${ }^{5}$ The relevant countries and territories are: Angola, Bhutan, Djibouti, Equatorial Guinea, Falkland Islands (Malvinas), Guinea-Bissau, Marshall Islands, Mayotte, Micronesia (Fed. States of), Montserrat, Nauru, Saint Kitts and Nevis, Saint-Pierre-et-Miquelon, Somalia, Swaziland and Western Sahara.
    ${ }^{6}$ The relevant countries and territories are: Andorra, Channel Islands, Holy See, Isle of Man, Monaco, Niue, Northern Mariana Islands, Saint Helena, Tokelau and Other non-specified areas. The total population of these countries and territories constituted less than 0.4 per cent of the global population of women aged 15 to 49 in 2010.

[^3]:    ${ }^{7}$ Calculations for the Model I pattern are based on the most recent data from Algeria, Hong Kong SAR of China, Macao SAR of China, Italy, Japan, Libya, Oman, the Republic of Korea and Spain. All countries in this group have late marriage patterns and low prevalence of consensual unions, which has not compensated for the decline in the proportion married in younger age groups. Thus, the proportion of women married or in-union at ages 20 to 24 and 25 to 29 is at lower levels.

[^4]:    ${ }^{8}$ Calculations for the Model II pattern are based on the most recent data from Australia, Austria, Canada, the Czech Republic, France, Germany, Hungary, the Netherlands, Norway, United Kingdom and the United States of America. In these countries, to a different degree, the increasing prevalence of consensual unions has partly compensated for the decline in proportion married in younger age groups in the past. All countries in this group have earlier union formation patterns compared to Model I, thus keeping the proportion of women married or in-union at ages 20 to 24 and 25 to 29 at higher levels. This model pattern is used both for countries with low and high prevalence of consensual unions. The important distinction compared to Model I is the earlier start of union formation, irrespective of the type of union.
