## **The 2004 Revision**

Highlights

United Nations  
New York, 2005

The Department of Economic and Social Affairs of the United Nations Secretariat is a vital interface between global policies in the economic, social and environmental spheres and national action. The Department works in three main interlinked areas: (i) it compiles, generates and analyses a wide range of economic, social and environmental data and information on which States Members of the United Nations draw to review common problems and take stock of policy options; (ii) it facilitates the negotiations of Member States in many intergovernmental bodies on joint courses of action to address ongoing or emerging global challenges; and (iii) it advises interested Governments on the ways and means of translating policy frameworks developed in United Nations conferences and summits into programmes at the country level and, through technical assistance, helps build national capacities.

#### **NOTE**

The designations employed in this report and the material presented in it do not imply the expression of any opinion whatsoever on the part of the Secretariat of the United Nations concerning the legal status of any country, territory, city or area or of its authorities, or concerning the delimitation of its frontiers or boundaries. The term “country” as used in the text of this report also refers, as appropriate, to territories or areas. The designations “more developed”, “less developed” and “least developed” countries, areas or regions are intended for statistical convenience and do not necessarily express a judgement about the stage reached by a particular country or area in the developing process.

## PREFACE

This report presents the highlights from the results of the *2004 Revision* of the official world population estimates and projections prepared by the United Nations Department of Economic and Social Affairs' Population Division. The *2004 Revision* is the nineteenth round of global demographic estimates and projections undertaken by the Population Division since 1950.

The full results of the *2004 Revision* will be presented in a series of three volumes currently under preparation. The first volume<sup>1</sup> will provide the comprehensive tables presenting the major demographic indicators for each country for 1950-2050; the second volume<sup>2</sup> will contain the distributions by age and sex of the population of each country for the period 1950-2050, and the third volume<sup>3</sup> will be devoted to an analysis of the results obtained.

Data will also be distributed in digital form. Interested users can purchase a CD-Rom containing the major results of the *2004 Revision*. A description of data contained in the CD-Rom and an order form will be posted on the web site of the Population Division at [www.unpopulation.org](http://www.unpopulation.org).

Responsibility for the *2004 Revision* rests with the Population Division. Preparation of the *2004 Revision* was facilitated by the collaboration of the regional commissions, the specialized agencies and other relevant bodies of the United Nations with the Population Division.

In particular, a major source of official national population statistics used in the preparation of these estimates and projections is the *United Nations Demographic Yearbook* and its accompanying databases, produced and maintained by the United Nations Statistics Division, Department of Economic and Social Affairs. The Population Division is grateful to the Statistics Division for its continuing cooperation.

Selected output from the *2004 Revision* as well as other population information may be accessed on the World Wide Web site of the Population Division at [www.unpopulation.org](http://www.unpopulation.org). For further information about the *2004 Revision*, please contact Ms. Hania Zlotnik, Director, Population Division, United Nations, New York, NY 10017, USA (Fax: 1 212 963 2147).

## EXPLANATORY NOTES

Tables presented in this report make use of the following symbols:

Two dots (..) indicate that data are not available or are not separately reported.

An em dash (—) indicates that the value is zero (magnitude zero).

A 0 or 0.0 indicates that the magnitude is not zero, but less than half of the unit employed.

A hyphen (-) indicates that the item is not applicable.

A minus sign (-) before a figure indicates a decrease.

A full stop (.) is used to indicate decimals.

Years given start on 1 July.

Use of a hyphen (-) between years, for example, 1995-2000, signifies the full period involved, from 1 July of the first year to 1 July of the second year.

Numbers and percentages in tables do not necessarily add to totals because of rounding.

Countries and areas are grouped geographically into six major areas: Africa; Asia; Europe; Latin America and the Caribbean; Northern America; and Oceania. These major areas are further divided into 21 geographical regions. In addition, for statistical convenience, the regions are classified as belonging to either of two categories: more developed or less developed. The less developed regions include all the regions of Africa, Asia (excluding Japan), and Latin America and the Caribbean, as well as Melanesia, Micronesia and Polynesia. The more developed regions comprise Australia/New Zealand, Europe, Northern America and Japan.

The group of least developed countries currently comprises 50 countries: Afghanistan, Angola, Bangladesh, Benin, Bhutan, Burkina Faso, Burundi, Cambodia, Cape Verde, Central African Republic, Chad, Comoros, Democratic Republic of the Congo, Democratic Republic of Timor-Leste, Djibouti, Equatorial Guinea, Eritrea, Ethiopia, Gambia, Guinea, Guinea-Bissau, Haiti, Kiribati, Lao People's Democratic Republic, Lesotho, Liberia, Madagascar, Malawi, Maldives, Mali, Mauritania, Mozambique, Myanmar, Nepal, Niger, Rwanda, Samoa, Sao Tome and Principe, Senegal, Sierra Leone, Solomon Islands, Somalia, Sudan, Togo, Tuvalu, Uganda, United Republic of Tanzania, Vanuatu, Yemen and Zambia.

The following abbreviations have been used:

AIDS	Acquired immunodeficiency syndrome
HIV	Human immunodeficiency virus
UNAIDS	Joint United Nations Programme on HIV/AIDS
ART	Antiretroviral therapy

## EXECUTIVE SUMMARY

The *2004 Revision* is the nineteenth round of official United Nations population estimates and projections prepared by the Population Division of the Department of Economic and Social Affairs of the United Nations Secretariat. These are used throughout the United Nations system as the basis for activities requiring population information. The *2004 Revision* is the first to incorporate the full results of the 2000 round of national population censuses. It also takes into account the results of recent specialized surveys carried out in developing countries to provide both demographic and other information to assess the progress made in achieving the internationally agreed development goals, including the Millennium Development Goals (MDGs). The comprehensive review of past worldwide demographic trends and future prospects presented in the *2004 Revision* provides the population basis for the assessment of those goals.

The *2004 Revision* confirms the variety of demographic dynamics of our times. While the population at the global level continues to increase, that of the more developed regions as a whole is hardly changing and virtually all population growth is occurring in the less developed regions. Especially rapid population growth characterizes the group of 50 least developed countries.

Underlying these varied patterns of growth are distinct trends in fertility and mortality. Below-replacement fertility prevails in the more developed regions and is expected to continue to 2050. Fertility is still high in most least developed countries and, although it is expected to decline, it will remain higher than in the rest of the world. In the rest of the developing countries, fertility has declined markedly since the late 1960s and is expected to reach below-replacement levels by 2050 in most of these developing countries.

Mortality in the established market economies of the developed world is low and continues to decline, but it has been stagnant or even increasing in a number of countries with economies in transition, largely as a result of deteriorating social and economic conditions and, in some cases, because of the spread of HIV. Mortality is also decreasing in the majority of developing countries, but in those highly affected by the HIV/AIDS epidemic, mortality has been increasing. Given the ongoing efforts to provide antiretroviral treatment to 3 million AIDS patients by 2005 and the expectation of further expansion of that treatment thereafter, the *2004 Revision* assumes a longer average survivorship for people living with HIV than the *2002 Revision* did and therefore projects somewhat lower future mortality levels in HIV-affected countries than the previous *Revision*.

The HIV/AIDS epidemic continues to spread. The number of countries with a significant number of infected people in the *2004 Revision* is 60, up from 53 in the *2002 Revision*. Although HIV prevalence levels in some countries have been revised downward as better statistics become available. Nevertheless, the toll of the disease continues to be high and is expected to remain so, despite projected reductions in the prevalence of HIV/AIDS. Lower projected levels of HIV prevalence depend on the realization of the commitments made by Governments in the 2000 Millennium Declaration<sup>4</sup> and the 2001 United Nations Declaration of Commitment on HIV/AIDS<sup>5</sup>.

---

<sup>4</sup> See General Assembly Resolution A/Res/55/2.

<sup>5</sup> See General Assembly Resolution A/Res/S-26/2.

The key findings from the *2004 Revision* can be summarized as follows:

1. By July 2005, the world will have 6.5 billion inhabitants, 380 million more than in 2000 or a gain of 76 million annually. Despite the declining fertility levels projected over 2005-2050 the world population is expected to reach 9.1 billion according to the medium variant and will still be adding 34 million persons annually by mid-century.
2. Today, 95 per cent of all population growth is absorbed by the developing world and 5 per cent by the developed world. By 2050, according to the medium variant, the population of the more developed countries as a whole would be declining slowly by about 1 million persons a year and that of the developing world would be adding 35 million annually, 22 million of whom would be absorbed by the least developed countries.
3. Future population growth is highly dependent on the path that future fertility takes. In the medium variant, fertility is projected to decline from 2.6 children per woman today to slightly over 2 children per woman in 2050. If fertility were to remain about half a child above the levels projected in the medium variant, world population would reach 10.6 billion by 2050. A fertility path half a child below the medium would lead to a population of 7.6 billion by mid-century. That is, at the world level, continued population growth until 2050 is inevitable even if the decline of fertility accelerates.

**Figure 1. Population of the world, 1950-2050, by projection variants**

Source: Population Division of the Department of Economic and Social Affairs of the United Nations Secretariat (2005). *World Population Prospects: The 2004 Revision. Highlights*. New York: United Nations.

4. Because of its low and declining rate of growth, the population of developed countries as a whole is expected to remain virtually unchanged between 2005 and 2050, at about 1.2

billion. In contrast, the population of the 50 least developed countries is projected to more than double, passing from 0.8 billion in 2005 to 1.7 billion in 2050. Growth in the rest of the developing world is also projected to be robust, though less rapid, with its population rising from 4.5 billion to 6.1 billion between 2005 and 2050.

**Figure 2. Population dynamics by development groups, 1950-2050**

Source: Population Division of the Department of Economic and Social Affairs of the United Nations Secretariat (2005). *World Population Prospects: The 2004 Revision. Highlights*. New York: United Nations.

5. Very rapid population growth is expected to prevail in a number of developing countries, the majority of which are least developed. Between 2005 and 2050, the population is projected to at least triple in Afghanistan, Burkina Faso, Burundi, Chad, Congo, the Democratic Republic of Congo, the Democratic Republic of Timor-Leste, Guinea-Bissau, Liberia, Mali, Niger and Uganda.
6. The population of 51 countries or areas, including Germany, Italy, Japan, the Baltic States and most of the successor states of the former Soviet Union, is expected to be lower in 2050 than in 2005.
7. During 2005-2050, nine countries are expected to account for half of the world's projected population increase: India, Pakistan, Nigeria, the Democratic Republic of Congo, Bangladesh, Uganda, the United States of America, Ethiopia and China, listed according to the size of their contribution to population growth during that period.
8. In 2000-2005, fertility at the world level stood at 2.65 children per woman, about half the level it had in 1950-1955 (5 children per women). In the medium variant, global fertility is projected to decline further to 2.05 children per woman by 2045-2050. Average world levels result from quite different trends by major development group. In developed countries as a whole fertility is currently 1.56 children per woman and is projected to

- increase slowly to 1.84 children per woman in 2045-2050. In the least developed countries, fertility is 5 children per woman and is expected to drop by about half, to 2.57 children per woman by 2045-2050. In the rest of the developing world, fertility is already moderately low at 2.58 children per woman and is expected to decline further to 1.92 children per woman by mid-century, thus nearly converging to the fertility levels by then typical of the developed world. Realization of the fertility declines projected is contingent on access to family planning, especially in the least developed countries.
9. In 2000-2005, fertility remains above 5 children per woman in 35 of the 148 developing countries, 30 of which are least developed countries, while the pace of decline in several countries of sub-Saharan Africa and South-central Asia has been slower than anticipated. Overall, the countries with high fertility account for 10 per cent of the world population. In contrast, fertility has reached below-replacement levels in 23 developing countries accounting for 25 per cent of the world population. This group includes China whose fertility during 2000-2005 is estimated at 1.7 children per woman.
  10. Fertility levels in the 44 developed countries, which account for 19 per cent of the world population, are currently very low. All except Albania have fertility below replacement level and 15, mostly located in Southern and Eastern Europe, have reached levels of fertility unprecedented in human history (below 1.3 children per woman). Since 1990-1995, fertility decline has been the rule among most developed countries. The few increases recorded, such as those in Belgium, France, Germany, the Netherlands and the United States, have been small.
  11. Global life expectancy at birth, which is estimated to have risen from 47 years in 1950-1955 to 65 years in 2000-2005, is expected to keep on rising to reach 75 years in 2045-2050. In the more developed regions, the projected increase is from 76 years today to 82 years by mid-century. Among the least developed countries, where life expectancy today is 51 years, it is expected to be 67 years in 2045-2050. Because many of these countries are highly affected by the HIV/AIDS epidemic, the projected increase in life expectancy is dependent on the implementation of effective programmes to prevent and treat HIV infection. In the rest of the developing world, under similar conditionalities, life expectancy is projected to rise from 66 years today to 76 years by mid-century.
  12. Mortality in Eastern Europe has been increasing since the late 1980s. In 2000-2005 life expectancy in the region, at 67.9 years, was lower than it had been in 1960-1965 (68.6 years). The Russian Federation and the Ukraine are particularly affected by rises in mortality resulting partly from the spread of HIV.
  13. Twenty-five years into the HIV/AIDS epidemic, the impact of the disease is evident in terms of increased morbidity and mortality and slower population growth. In Southern Africa, the region with the highest HIV/AIDS prevalence of the disease, life expectancy has fallen from 62 years in 1990-1995 to 48 years in 2000-2005, and is projected to decrease further to 43 years over the next decade before a slow recovery starts. As a consequence, population growth in the region is expected to stall between 2005 and 2020. In Botswana, Lesotho and Swaziland, the population is projected to decrease as deaths outnumber births. In most of the other developing countries affected by the epidemic, population growth will continue to be positive because their moderate or high fertility more than counterbalances the rise in mortality.
  14. The primary consequence of fertility decline, especially if combined with increases in life expectancy, is population ageing, whereby the share of older persons in a population grows relative to that of younger persons. Globally, the number of persons aged 60 years or over is expected almost to triple, increasing from 672 million in 2005 to nearly 1.9

- billion by 2050. Whereas 6 out of every 10 of those older persons live today in developing countries, by 2050, 8 out of every 10 will do so. An even more marked increase is expected in the number of the oldest-old (persons aged 80 years or over): from 86 million in 2005 to 394 million in 2050. In developing countries, the rise will be from 42 million to 278 million, implying that by 2050 most oldest-old will live in the developing world.
15. In developed countries, 20 per cent of today's population is aged 60 years or over and by 2050 that proportion is projected to be 32 per cent. The elderly population in developed countries has already surpassed the number of children (persons aged 0-14) and by 2050 there will be 2 elderly persons for every child. In the developing world, the proportion of the population aged 60 or over is expected to rise from 8 per cent in 2005 to close to 20 per cent by 2050.
  16. Increases in the median age, the age at which 50 per cent of the population is older and 50 per cent younger than that age, are indicative of population ageing. Today, just 11 developed countries have a median age above 40 years. By 2050, there will be 90 countries in that group, 46 in the developing world. Population aging, which is becoming a pervasive reality in developed countries, is also inevitable in the developing world and will occur faster in developing countries.
  17. Countries where fertility remains high and has declined only moderately will experience the slowest population ageing. By 2050, about one in five countries is still projected to have a median age equal or less than 30 years. The youngest populations will be found in least developed countries, 11 of which are projected to have median ages equal to or less than 23 years in 2050, including Afghanistan, Angola, Burundi, Chad, the Democratic Republic of Congo, Equatorial Guinea, Guinea-Bissau, Liberia, Mali, Niger and Uganda.
  18. During 2005-2050, the net number of international migrants to more developed regions is projected to be 98 million or an average of 2.2 million annually. The same number will leave the less developed regions. For the developed world, such a level of net migration will largely offset the expected excess of deaths over births during 2005-2050, which amounts to a loss of 73 million people. For the developing world, the 98 million emigrants represent scarcely less than 4 per cent of expected population growth.
  19. Over the period 2000-2005, 74 countries were net receivers of migrants. In 64 of these countries, the net migration projected reinforces population growth and in 7 countries, it reverses the trend of population decline (Austria, Croatia, Germany, Greece, Italy, Slovakia and Slovenia) In three countries, the migration slows down population decline but does not reverse it (Czech Republic, Hungary and the Russian Federation).
  20. In terms of annual averages for the period 2005-2050, the major net receivers of international migrants are projected to be the United States (1.1 million annually), Germany (202,000), Canada (200,000), the United Kingdom (130,000), Italy (120,000) and Australia (100,000). The major countries of net emigration are projected to be China (-327,000 annually), Mexico (-293,000), India (-241,000), the Philippines (-180,000), Indonesia (-164,000), Pakistan (-154,000) and the Ukraine (-100,000).

## I. WORLD POPULATION TRENDS

### A. POPULATION SIZE AND GROWTH

On 1 July 2005, the world population will reach 6.5 billion, 5.3 billion of whom (or 81 per cent) live in the less developed regions (table I.1). Out of these, 759 million reside in the 50 least developed countries and account for nearly 12 per cent of the world population. More developed countries, with 1.2 billion inhabitants, account for 19 per cent of the world population (table I.2).

According to the medium variant, by 2050 the world population is projected to reach 9.1 billion persons, that is, 2.6 billion more than in 2005, an increase equivalent of the combined populations of today's China and India. Most of this growth will be absorbed by developing countries. Between 2005 and 2050, the population of the more developed regions will remain largely unchanged at 1.2 billion inhabitants, but the population of the less developed regions would have risen to 7.8 billion. At the same time, the population of the least developed countries would more than double, reaching 1.7 billion. Consequently, by 2050, 86 per cent of the world population is expected to live in the less developed regions, including 19 per cent in the least developed countries, whereas only 14 per cent will live in the more developed regions.

Source: Population Division of the Department of Economic and Social Affairs of the United Nations Secretariat (2005). *World Population Prospects: The 2004 Revision. Highlights*. New York: United Nations.

World population in 2050 would be substantially higher in the absence of the declines of fertility anticipated by the medium variant. If fertility were to remain constant at current levels in all countries, the world population would almost double by 2050, reaching 11.7 billion. In the high variant, where fertility is assumed to remain mostly half a child higher than in the medium variant, the world population in 2050 would reach 10.6 billion. In the low variant, where fertility is projected to be half a child lower than in the medium variant, world population would still grow, but only to reach 7.7 billion by 2050. In the low variant, the population of the least developed countries will still double, to 1.5 billion, but the population of the more developed regions would decline to less than 1.1 billion.

Most of the world's population lives in a few countries. Four out of every 10 inhabitants on earth live in China or India. A further 8 countries account for another 2 out of every 10 of the earth's inhabitants, namely, the United States of America, Indonesia, Brazil, Pakistan, Russian Federation, Bangladesh, Nigeria and Japan (table VIII.3). However, most of the countries of the world have small populations. Thus, 77 per cent of the 228 countries or areas covered by the 2004 Revision have populations of less than 20 million inhabitants and taken together account for only 11 per cent of the world's population. By 2050, India will have surpassed China in population size and the two will account for about 33 per cent of the world's population. In addition, three least developed countries—Bangladesh, the Democratic Republic of the Congo and Ethiopia—will be among the ten most populous countries.

Increments in the world population are also largely concentrated in a few countries, generally the most populous. Thus, during 2005-2050, 9 countries—India, Pakistan, Nigeria, the Democratic Republic of the Congo, Bangladesh, Uganda, the United States of America, Ethiopia and China, in order of population increment—are expected to account for almost half of the world's projected population increase.

**Figure 3. Average annual rate of change of the population of the world and major development groups, 1950-2050 (medium variant)**

Source: Population Division of the Department of Economic and Social Affairs of the United Nations Secretariat (2005). *World Population Prospects: The 2004 Revision. Highlights*. New York: United Nations.

Throughout human history, the growth rate of the world population was generally very low. Growth rates started to increase slowly in the XVII or XVIII centuries as mortality began to decline. At the world level, the population growth rate rose rapidly in the XX century, reaching a peak at 2 per cent per year in 1965-1970. Since then, the growth rate of the world population has been declining, largely as a result of the reduction of fertility in the developing world, so that it

reached 1.21 per cent per year in 2000-2005 and is expected to drop further to 0.37 per cent per year by 2045-2050.

However, because fertility decline has not occurred simultaneously in all countries, the pace of population growth still differs considerably among development groups. Thus, whereas today the population of the more developed regions is rising at an annual rate of 0.3 per cent, that of the less developed regions is increasing almost five times as fast, at 1.4 per cent annually, and the least developed countries as a group are experiencing even more rapid population growth at 2.4 per cent per year. Such differences, although somewhat dampened, will persist until 2050. By that time, according to the medium variant, the population of the more developed regions will have been declining for 20 years, whereas the population of the less developed regions will still be rising at an annual rate of 0.4 per cent. More importantly, the population of the least developed countries will likely be increasing at a robust annual rate of 1.3 per cent in 2045-2050, a rate that, if maintained, would lead to a doubling of the population every 54 years.

TABLE I.2. DISTRIBUTION OF THE WORLD POPULATION BY DEVELOPMENT GROUPS AND MAJOR AREAS, AND PROJECTION VARIANTS, 1950-2050

Major area	1950	1975	2005	2050

## B. POPULATION AGE COMPOSITION

The primary demographic consequence of fertility decline, especially if combined with increases in life expectancy, is population ageing. As a population ages, the proportion of older people in the population increases and that of younger persons declines. In 1950, just 8 per cent of the world population was aged 60 years or over. By 2005 that proportion had risen to 10 per cent and it is expected to more than double over the next 45 years, reaching 22 per cent in 2050 (table VIII.10). Globally, the number of older persons (aged 60 years or over) will nearly triple in size, increasing from 673 million in 2005 to almost 2 billion by 2050. In contrast, the number of children (persons aged 0-14 years) worldwide will change little over the next 45 years, passing from 1.82 billion to 1.83 billion and their share of the total population will drop from 28 per cent to 20 per cent.

Increases in the median age, the age at which 50 per cent of the population is older and 50 per cent is younger than that age, are indicative of the ageing of the population. Today, 11 countries, all of them belonging to the more developed regions, have a median age of over 40

years. Leading this group is Japan with a median age of 43 years, followed closely by Italy and Germany, both with a median age of 42 years (table VIII.11). By 2050, there will be 90 countries with a median age over age 40, 46 in the developing world. That is, population aging, which is a pervasive reality in developed countries, is expected also to become common in the developing world especially as it occurs over a shorter time span than in developed countries.

Despite the general trend toward population ageing, countries that still have relatively high fertility will have a younger population than the rest by 2050. Mostly least developed countries are in this group. In 2050, the youngest populations will be found in 11 least developed countries whose median ages are projected to be at or below 23 years. These countries include Angola, Burundi, Chad, the Democratic Republic of Congo, Equatorial Guinea, Guinea-Bissau, Liberia, Niger and Uganda. Today, the median age in Mali, Niger and Uganda is 16 years or less, making their populations the youngest in the planet.

The more developed regions have been leading the process of population ageing and their experience provides a point of comparison for the expected ageing of the population of less developed regions. In 1950, the number of children in the more developed world was twice as large as the number of older persons, with children accounting for 27 per cent of the total population and the elderly for only 12 per cent. By 2005, the proportion of older persons in the more developed regions had surpassed that of children (20 per cent versus 17 per cent) and in 2050, the proportion of older persons is expected to be double that of children (32 per cent versus 16 per cent). In 2050, the number of elderly persons in more developed regions is projected to be more than four times larger than estimated for 1950 (95 million in 1950 versus 400 million in 2050) while the number of children is anticipated to decline from 222 million in 1950 to 193 million in 2050.

Until 2005, population aging had been considerably slower in the less developed regions where fertility is still relatively high. The proportion of children had declined from 38 per cent in 1950 to 31 per cent in 2005, while the proportion of older persons had increased from 6 per cent to 8 per cent. However, a period of more rapid population aging lies ahead for the less developed regions. By 2050, the proportion of older persons in those regions is expected to rise to 20 per cent, whereas the proportion of children is expected to decline to 21 per cent.

Trends in the number of persons of working age (aged between 15 and 59 years) are particularly important for all countries. The proportion of the population in those ages is an important factor related to the potential for economic growth. In more developed regions, the proportion of the population of working age increased between 1950 and 2005, but only slightly (from 61 per cent in 1950 to 63 per cent in 2005). However, it is expected to decline in the future, reaching 52 per cent by 2050. In the less developed regions as a whole, the proportion of the population of working age is expected to decline slightly, passing from 61 per cent in 2005 to 59 per cent in 2050. However, among the least developed countries, that proportion will rise from 53 per cent in 2005 to 61 per cent in 2050, an increase that represents both an opportunity and a challenge: the opportunity for economic growth provided that the challenge of creating gainful employment for the growing share of persons of working age is met.

Among the older population, the number and proportion of the oldest-old, that is, persons aged 80 years or over, is rising. In 2005, there were 87 million oldest-old, comprising 1.3 per cent of the world's population. By 2050, this segment of the population is projected to reach 394 million or 4.3 per cent of the total population. The oldest-old is the fastest growing segment of the world population (table I.3). Particularly rapid increases in this segment of the population are expected in the less developed regions where the oldest-old are projected to rise from 42 million in 2005 to 279 million in 2050 implying an average annual rate of 4.2 per cent. By 2050, 71 per cent of all the oldest-old will be living in less developed regions.

TABLE I.3. AVERAGE ANNUAL RATE OF CHANGE OF THE TOTAL POPULATION AND THE POPULATION IN BROAD AGE GROUPS, BY MAJOR AREA, 2005-2050 (MEDIUM VARIANT)

In 64 countries, the proportion of oldest-old was higher than at the world level in 2005 (1.3 per cent). This group was led by Belgium, France, Italy, Japan, Norway and Sweden in which more than 5 per cent of the population were aged 80 years or over. By 2050, 91 countries are expected to have a greater share of their population 80 years or older than at the world level (4.3 per cent). In 19 of those countries, led by Japan and Italy, the proportion of oldest-old will constitute over 10 per cent of the population.

As the rest of the population, the oldest-old tend to be concentrated in the most populous countries. In 2005, 14.8 million lived in China, 10.6 million in India and 8.4 million in the United States of America. In 2050, those countries will still have the largest numbers of oldest-old: China with 100.5 million, India with 52.9 million and the United States of America with 28.7 million.

## II. FERTILITY

According to the *2004 Revision*, total fertility—that is, the average number of children a woman would bear if fertility rates remained unchanged during her lifetime—was 2.65 children per woman in 2000-2005 at the world level (table II.1). This average masks the heterogeneity of fertility levels among countries. In 2000-2005, 65 countries or areas (43 of them located in the more developed regions) had fertility levels below 2.1 children per woman or replacement level<sup>6</sup>, whereas 127 countries or areas (126 of which are located in the less developed regions) had total fertility levels at or above 2.1 children per woman. Among the later, 35 had total fertility levels at or above 5 children per woman, 30 of which are least developed countries (table II.2).

TABLE II.1. TOTAL FERTILITY FOR THE WORLD, MAJOR DEVELOPMENT GROUPS AND MAJOR AREAS, 1970-1975, 2000-2005 AND 2045-2050, BY PROJECTION VARIANTS

Major area	Total fertility (children per woman)					
	1970-1975	2000-2005	2045-2050			
			Low	Medium	High	Constant
World.....	4.49	2.65	1.56	2.05	2.53	3.50

Source: Population Division of the Department of Economic and Social Affairs of the United Nations Secretariat (2005). *World Population Prospects: The 2004 Revision. Highlights*. New York: United Nations.

In 2005, the 65 countries where total fertility was below replacement level accounted for 43 per cent of the world's population, or 2.8 billion people, whereas the countries with fertility at or above replacement level had 3.6 billion persons in 2005, or 57 per cent of the total. Because of their low fertility and the expectation that it will not rise markedly in the future, the countries with below-replacement fertility are projected to have only a slightly larger population in 2050 than today (2.9 billion people). In contrast, the countries whose fertility is currently above replacement level are expected to experience a marked population increase, reaching 6.1 billion by 2050 and accounting then for 68 per cent of the global population.

In the 30 years since the first World Population Conference held in Bucharest, Romania, in 1974 fertility has declined by 20 per cent or more in 121 developing countries and in 49 of them the decline exceeded 50 per cent. Consequently, women in those countries have on average today half the number of children their mothers had. Countries having the fastest fertility reductions are mostly in Asia (Hong Kong (China SAR), Macao (China SAR), Iran, Kuwait, Mongolia, Thailand, the Republic of Korea and Viet Nam), but they also include Algeria and Tunisia in Northern Africa and Mexico in Latin America. The average number of children in

<sup>6</sup> Replacement-level fertility is the level that needs to be sustained over the long run to ensure that a population replaces itself. For most countries, replacement level is close to 2.1 children per woman.

those countries is currently below 2.5 children per woman compared to 5 or more a generation ago (table VIII.14).

TABLE II.2. DISTRIBUTION OF COUNTRIES AND AREAS OF THE WORLD POPULATION ACCORDING TO THE LEVEL OF TOTAL FERTILITY IN 1950-1955, 1970-1975, 2000-2005 AND 2045-2050 (MEDIUM VARIANT)

While fertility was uniformly high in the less developed countries in the 1970s (110 out of the 148 developing countries had on average more than 5 children per woman), the pace of fertility decline has varied significantly among them. During 1995-2005, the pace of decline was faster than anticipated in three Asian countries with high fertility (the Maldives, Oman and Pakistan) where the average number of children per woman declined by 15 per cent or more (table VIII.15). However, the rapid declines that were previously assumed to have taken place in several countries had not materialized. These countries included Cape Verde, Kenya, and South Africa in Africa, Bangladesh, Tajikistan and Uzbekistan in South-central Asia, Indonesia in South-eastern Asia, and the Federated States of Micronesia and Samoa in Oceania. In addition, fertility in the Democratic Republic of Timor-Leste increased instead of declining over the past decade. For this country, the recent increase of fertility from about 5 children per woman to almost 8 children per woman is likely to be temporary, associated as it is to the political changes that have occurred since the 1999 referendum and the independence of the Democratic Republic of Timor-Leste from Indonesia in 2002.

Although most developing countries are already far advanced in the transition from high to low fertility, 17 still had fertility levels of 6 children per woman or higher in 2000-2005 and for 15 of them there is either no recent evidence about fertility trends or the available evidence does not indicate the onset of a fertility reduction. Although the fertility of those 17 countries is projected to decline after 2010 at a pace of about one child per decade, none is expected to reach 2.1 children per woman by 2050 in the medium variant. As a result of those trends, their population is expected to rise from 250 million in mid-2005 to 791 million in 2050.

**Figure 4. Total fertility trajectories of the world and major development groups, 1950-2050 (medium variant)**

Source: Population Division of the Department of Economic and Social Affairs of the United Nations Secretariat (2005). *World Population Prospects: The 2004 Revision. Highlights*. New York: United Nations.

With the sole exception of the Congo, the 17 countries involved—Afghanistan, Angola, Burkina Faso, Burundi, Chad, Congo, Democratic Republic of the Congo, Democratic Republic of Timor-Leste, Guinea-Bissau, Liberia, Malawi, Mali, Niger, Sierra Leone, Somalia, Uganda, Yemen—are all least developed countries and several are already highly affected by the HIV/AIDS epidemic. Moreover, a number of them have been experiencing civil strife and political instability in recent years, factors that militate against the provision of basic services for the population. Clearly, the continuation of rapid population growth poses serious challenges to their future development.

Despite the importance that high-fertility countries have for the future of world population, in 2000-2005 they accounted for less than 4 per cent of that population and are expected to account for 9 per cent by 2050 according to the medium variant. The share of countries with total fertility levels ranging from 4 to 6 children per woman was also small, accounting for 11 per cent of the world population in 2005 (table II.2). In 2000-2005, the bulk of the population of the developing world lived in 71 countries where total fertility levels ranged from 2.1 to 4 children per woman, countries that accounted for 42 per cent of the world population. In the *2004 Revision*, the total fertility of those countries is projected to decline below 2.1 children per woman by 2050, that is, their future fertility is no longer constrained to remain at replacement level (2.1 children per woman) once that level reached. Although 20 countries whose fertility in 2000-2005 was within the range of 2.1 to 4 children per woman do not reach the floor level of 1.85 children per woman, the majority does. Consequently, by 2045-2050, the medium variant projects that 78 per cent of the world's population will live in countries or areas with a

total fertility below 2.1 children per woman. A total of 148 countries or areas will be in that group, among which 120 are projected to have a total fertility equal or lower to 1.85 children per woman in 2045-2050. The remaining 44 countries or areas are projected to have total fertility levels at or above 2.1 children per woman in 2045-2050. By that time, they will account for 22 per cent of the world's population, compared to 14 per cent in 2005.

Fertility levels in developed countries, many of which experienced a "baby-boom" during the 1950s and 1960s, have generally declined since the 1970s to below-replacement level. While in 1970-1975, 18 countries out of the 44 developed countries in the world already had below-replacement fertility, all but one (Albania) have had below-replacement fertility levels since 1995-2000. Between 1995-2000 and 2000-2005 alone, fertility has continued to decline by 3 per cent or more in 21 developed countries, while it increased by 3 per cent or more in 10 developed countries. As of 2000-2005, fertility had reached historically unprecedented low levels (below 1.3 children per woman) in 15 developed countries, all located in Southern and Eastern Europe.

At the world level, total fertility in 2045-2050 is expected to be 2.05 children per woman according to the medium variant (table II.1), the result of 1.84 children per woman in the more developed regions and 2.07 children per woman in the less developed regions. That is, although the difference in total fertility between the more and the less developed regions narrows considerably by mid-century, the less developed regions as whole are still expected to have a higher total fertility than the more developed regions. That difference persists in all projection variants. Total fertility in the low variant is expected to be 1.34 children per woman in the more developed regions and 1.59 in the less developed regions. In the high variant, total fertility is projected to be 2.34 in the more developed regions and 2.56 in the less developed regions.

### III. MORTALITY AND THE DEMOGRAPHIC IMPACT OF HIV/AIDS

#### A. TRENDS AND PROSPECTS IN WORLD MORTALITY

The twentieth century witnessed the most rapid decline in mortality of human history. By 1950-1955, life expectancy at the world level was 47 years and it had reached 65 years by 2000-2005. Over the next 45 years, life expectancy at the global level is expected to rise further to reach 75 years in 2045-2050 (table III.1). The more developed regions already had a high expectation of life in 1950-1955 (66 years) and have since experienced further gains in longevity. By 2000-2005 their life expectancy stood at 76 years, 13 years higher than in the less developed regions where the expectation of life at birth was 63 years. Although the gap between the two groups is expected to narrow between 2005 and mid-century, in 2045-2050 the more developed regions are still expected to have considerably higher life expectancy at birth than the less developed regions (82 years versus 74 years).

TABLE III.1. LIFE EXPECTANCY AT BIRTH FOR THE WORLD, MAJOR DEVELOPMENT GROUPS AND MAJOR AREAS, 2000-2005 AND 2045-2050

Oceania .....	74.0	81.2

*Source:* Population Division of the Department of Economic and Social Affairs of the United Nations Secretariat (2005). *World Population Prospects: The 2004 Revision. Highlights*. New York: United Nations.

The 50 least developed countries, which include 31 of the countries that are highly affected by HIV/AIDS, have been experiencing higher mortality than other development groups. Their life expectancy at birth was 51 years in 2000-2005 and is expected to remain relatively low, reaching 67 years in 2045-2050.

The general upward trend in life expectancy for the more developed and the less developed regions conceals varying trends among the world's major areas (figure 6). In Asia, Latin America and the Caribbean, Northern America and Oceania, life expectancy has been increasing at a steady pace. In contrast, Europe as a whole experienced a slowdown in life expectancy increase starting in the late 1960s and stagnating levels since the late 1980s. This stagnating trend is strongly influenced by severe declines in life expectancy in Eastern Europe, particularly in the Russian Federation and the Ukraine. The remaining regions of Europe have life expectancies equal to or higher than that for Northern America.

**Figure 5. Life expectancy at birth for the world and major development groups, 1950-2050**

Source: Population Division of the Department of Economic and Social Affairs of the United Nations Secretariat (2005). *World Population Prospects: The 2004 Revision. Highlights*. New York: United Nations.

Africa, unlike other major areas, has been experiencing declining life expectancy since the late 1980s. While this trend is due in large part to the HIV/AIDS epidemic, other factors have also played a role, including armed conflict, economic stagnation, and resurgent infectious diseases such as tuberculosis and malaria. The recent negative trends in Africa have set back progress in reducing mortality by at least 25 years. Not until 2010-2015 are life expectancy levels in Africa expected to return to those last seen in 1985-1990. By 2045-2050, life expectancy in Africa is expected to be 65 years, a full 12 years below the life expectancy of the next lowest major area, Asia.

**Figure 6. Life expectancy at birth for the world and major areas, 1950-2050**

Source: Population Division of the Department of Economic and Social Affairs of the United Nations Secretariat (2005). *World Population Prospects: The 2004 Revision. Highlights*. New York: United Nations.

In nearly all countries of the world, the life expectancy at birth of females is higher than that of males. At the world level, females had a life expectancy of 68 years in 2000-2005, compared to 63 years for males (table III.2). The female advantage is considerably larger in the more developed regions (7 years) than in the less developed regions (3 years). The gap between male and female life expectancy is particularly narrow in the least developed countries (2 years), where the impact of HIV/AIDS on mortality is estimated to be more detrimental for women. In 2045-2050, the difference between female and male life expectancy at the world level is expected to remain at about 5 years in favour of females. The female to male gap is expected to narrow in the more developed regions and widen in the less developed regions.

TABLE III.2. LIFE EXPECTANCY BY SEX, WORLD AND MAJOR DEVELOPMENT GROUPS, 2000-2005 AND 2045-2050

Major area	Life expectancy at birth (years)			
	2000-2005		2045-2050	
	Male	Female	Male	Female
World .....	63.2	67.7	72.8	77.5
More developed regions .....	71.9	79.3	79.1	85.0
Less developed regions .....	61.7	65.2	71.8	76.2

Figure 7. Child mortality for the world and selected regions, 1950-2050

Source: Population Division of the Department of Economic and Social Affairs of the United Nations Secretariat (2005). *World Population Prospects: The 2004 Revision. Highlights*. New York: United Nations.

Child mortality, measured as the proportion of children born alive surviving to age five, is an important indicator of development and the well-being of children. In 1950-1955, almost a quarter (224 per 1,000) of all children born worldwide did not reach their fifth birthday. By 2000-2005, this rate had fallen to 86 per 1,000. Although child mortality has fallen in all major areas, sub-Saharan Africa has lagged behind other major areas in the transition to low child mortality. Figure 7 compares under-five mortality in sub-Saharan Africa to that of South-central Asia. The two areas had similarly high and declining levels of child mortality in the 1950s, but in the 1980s the pace of decline in sub-Saharan Africa began to lessen. By 2000-2005, under-five mortality

had reached 98 per 1,000 in South-central Asia, but it was still 173 per 1,000 in sub-Saharan Africa.

## B. THE DEMOGRAPHIC IMPACT OF AIDS

Twenty-five years into the HIV/AIDS epidemic, its impact on the populations of the highly-affected countries is becoming increasingly evident. In the *2004 Revision*, the impact of HIV/AIDS is explicitly modelled for 60 countries, up from 53 in the *2002 Revision*. In most of these countries, HIV prevalence in 2003 was estimated to be 1 per cent or higher among the population aged 15-49 (table VIII.21). Four populous countries with lower prevalence levels were also included because they had a large number of persons living with HIV, namely, Brazil, China, India and the United States of America.

Of the 60 highly-affected countries, 40 are in sub-Saharan Africa, five in Asia, 12 in Latin America and the Caribbean, two in Europe, and one in Northern America. Together they account for 33.6 million of the 35.7 million HIV-infected adults in the world in 2003 or 94 per cent of the total.

The dynamics of the HIV/AIDS epidemic as reflected in the *2004 Revision* are fully consistent with the estimates of HIV prevalence in each country in 2003 as reported by UNAIDS.<sup>7</sup> Beginning in 2005, the *2004 Revision* assumes that changes in behaviour, along with treatment, will reduce the chances of infection. Rates of recruitment into high-risk groups are assumed to decline as well. In light of major expansions in antiretroviral therapy (ART) coverage, survival of individuals receiving ART is assumed to increase at a rate determined by projected levels of ART coverage and efficacy. The epidemic is still expanding, and some countries are expected to see increasing levels of HIV prevalence for several more years. Nevertheless, in 49 of the 60 highly-affected countries, HIV prevalence is projected to be lower in 2015 than in 2003 (table VIII.21).

In the *2004 Revision*, the projected long-term impact of HIV/AIDS is somewhat less severe than that projected in the *2002 Revision*. Part of this reduction is due to the incorporation of revised and lower estimates of HIV prevalence for several countries. Another part stems from the assumption that antiretroviral therapy will reach an ever increasing proportion of the persons who need it and that, as a result, those persons will not only survive longer but will be less infectious. However, realization of these projections is contingent on sustained commitment by Governments to assure treatment for those infected and to promote preventive measures and behavioural changes among the uninfected.

The *2004 Revision* confirms yet again the devastating toll AIDS has in terms of increased morbidity, mortality, and population loss. Life expectancy in the most affected countries already shows dramatic declines. In Botswana, where HIV prevalence is estimated at 36 per cent of the adult population in 2003, life expectancy has fallen from 65 years in 1985-1990 to 37 years in 2000-2005. In Southern Africa as a whole, where most of the worst affected countries are, life expectancy has fallen from 61 to 48 years over the same period. Furthermore, the impact of HIV/AIDS on life expectancy is projected to worsen still further before lessening. While the impact in Southern Africa is particularly stark, the majority of highly affected countries in Africa have experienced declines in life expectancy in recent years because of the epidemic.

In countries where HIV prevalence rates are lower, AIDS has mainly slowed down the increase in life expectancy. To assess the impact of the disease on life expectancy in these countries, the medium variant projections are compared with a hypothetical scenario in which

---

<sup>7</sup> Report on the Global HIV/AIDS epidemic 2004 (Geneva, UNAIDS, 2004).

AIDS does not exist (table VIII.22). One can thus conclude that in 2000-2005, for instance, life expectancy is lower than it would have been in the absence of AIDS by 4 years in Cambodia, 3 years in the Dominican Republic, and 2 years in Ukraine. A still larger impact is yet to come in many countries, such as China, where the impact of AIDS on life expectancy relative to the No-AIDS scenario is projected to rise from a gap of 0.3 years in 2000-2005 to 1.2 years in 2015-2020. Similarly, in the Russian Federation, such a measure of impact will rise from 1 year in 2000-2005 to 3 years by 2015-2020.

The gender dimension of the impact of AIDS is particularly important in sub-Saharan Africa, where women are infected with HIV at younger ages and in greater numbers than men. As a result of these infection patterns, the impact of AIDS on life expectancy is larger for females than for males. In four countries—Kenya, Malawi, Zambia, and Zimbabwe—female life expectancy fell below male life expectancy by 2000-2005 due to AIDS. The greatest difference occurs in Kenya, where female life expectancy is currently lower than male life expectancy by two years (46 for women compared to 48 for men). By 2010-2015, the list of countries with lower female life expectancy will expand to include most of the countries where HIV prevalence is currently above 10 per cent.

The toll that HIV/AIDS is taking is already retarding progress in reducing child mortality. Thirty-three per cent of children infected through mother-to-child transmission are estimated to die before their first birthday, and 61 per cent die by age five. The impact of HIV on child mortality is particularly dramatic in countries that had achieved relatively low levels of child mortality before the epidemic began. In Botswana, for instance, where under-five mortality was one of the lowest levels in sub-Saharan Africa, it has risen from 62 child deaths per 1,000 live births in 1990-1995 to 106 per 1,000 in 2000-2005. In Swaziland, under-five mortality has risen from 109 to 143 deaths per 1,000 over the same interval. The impact on child mortality is projected to decrease in the future with improved prevention of mother-to-child transmission.

AIDS reshapes the percentage distribution of deaths by age. In 1985-1990, deaths in Southern Africa were concentrated among young children and older adults (figure 8), and adults aged 20 to 49 accounted for only 20 per cent of all deaths. By 2000-2005, a dramatic shift had taken place in the distribution of deaths by age, with nearly 60 per cent of all deaths occurring between the ages of 20 and 49. Such large increases in mortality deplete the cohorts that are in the prime of their working and parental careers, creating the potential for severe shocks to economic and societal structures.

**Figure 8. Percentage distribution of deaths by age, Southern Africa, 1985-1990 and 2000-2005**

Source: Population Division of the Department of Economic and Social Affairs of the United Nations Secretariat (2005). *World Population Prospects: The 2004 Revision. Highlights*. New York: United Nations.

The concentration of AIDS mortality among women and working-age adults will reshape the age structure of populations in the affected countries of Africa. The effect on the age and sex structure of the population of Zimbabwe in 2015 is shown in figure 9. The age distribution resulting from the No-AIDS scenario is superimposed on the population projected under the medium variant. The adult population projected to 2020 is a small fraction of the population that would have been expected in the absence of AIDS. The reduced size of younger cohorts stems from the deaths of large numbers of women during the reproductive ages. Total population in Zimbabwe in 2015 is projected to be 4.8 million or 26 per cent lower than in the no-AIDS scenario.

**Figure 9. Population in 2015, with AIDS and without AIDS, by sex and age group, Zimbabwe**

**TABLE III.3. DIFFERENCE IN PROJECTED POPULATION IN THE MEDIUM VARIANT VERSUS A NO-AIDS SCENARIO FOR GROUPS OF AFFECTED COUNTRIES, 2005, 2015 AND 2050**

Group of countries	Population difference (thousands)			Percentage difference		
	2005	2015	2050	2005	2015	2050
All 60 affected countries .....	49 335	114 852	344 466	1.2	2.5	5.8
40 countries in Africa .....	36 156	84 119	266 218	4.8	8.5	14.0
5 countries in Asia.....	9 795	23 227	61 973	0.4	0.8	1.9
12 countries in Latin America and the Caribbean.....	1 730	3 048	6 661	0.7	1.2	2.0

Source: Population Division of the Department of Economic and Social Affairs of the United Nations Secretariat (2005). *World Population Prospects: The 2004 Revision. Highlights*. New York: United Nations.

Altogether, the 60 countries highly affected by the HIV/AIDS epidemic will have a total population in 2015 that is 115 million lower than in a no-AIDS scenario (table III.3). This difference is expected to grow to 344 million by 2050. Nearly three-quarters of the difference in 2050 is attributable to African countries. Despite the negative impact of the epidemic on population growth rates, however, the populations of affected countries are generally expected to be larger by mid-century than today, mainly because most of them maintain high to moderate fertility levels. Only the three countries with the highest prevalence in 2003—Swaziland, Botswana, and Lesotho—are expected to experience negative population growth rates mostly attributable to excess mortality due to AIDS.

## IV. INTERNATIONAL MIGRATION

Estimates of net migration between the major development groups show that since 1960 the more developed regions have been net gainers of emigrants from the less developed regions (table IV.1). Furthermore, net migration to the more developed regions has been increasing steadily from 1960 to 2000. During 1990-2000, the more developed regions were gaining annually 2.6 million migrants. About half of that net flow was directed to Northern America (1.3 million annually). During 2000-2010, the level of net migration to the more developed regions as a whole changes only slightly, but there is some increase in the net number of migrants received by Northern America (1.4 million annually). Over the rest of the projection period, net migration to the more developed regions is projected to remain at about 2.2 million per year, of which 1.3 million are directed to Northern America.

With respect to the other major areas, Asia was by far the major source of migrants during 1990-2000 (1.4 million annually), followed by Latin America and the Caribbean (0.8 million annually) and then Africa (0.3 million annually). After 2000, over half of all migrants leaving the less developed regions are expected to be from Asia, about 25 per cent to 30 per cent from Latin America and the Caribbean and the remaining from Africa.

TABLE IV.1. AVERAGE ANNUAL NET NUMBER OF MIGRANTS PER DECADE BY DEVELOPMENT GROUPS AND MAJOR AREAS, 1950-2050 (MEDIUM VARIANT)

<i>Major area</i>	<i>Net number of migrants (thousands)</i>						
	<i>1950-1960</i>	<i>1960-1970</i>	<i>1970-1980</i>	<i>1980-1990</i>	<i>1990-2000</i>	<i>2000-2010</i>	<i>2040-2050</i>

*Source:* Population Division of the Department of Economic and Social Affairs of the United Nations Secretariat (2005). *World Population Prospects: The 2004 Revision. Highlights*. New York: United Nations.

At the country level, during 1990-2000, 34 of the 44 developed countries have been net receivers of international migrants. This group includes traditional countries of immigration such as Australia, Canada, New Zealand and the United States of America, most of the populous countries in Northern, Southern and Western Europe as well as the Russian Federation and Japan. The movement of people from less developed regions to more developed regions has dominated the world migration patterns for almost half a century, but these flows have not been exclusively unidirectional. Several countries or areas in the less developed regions have been attracting migrants in large numbers, including Hong Kong (China SAR), Israel, Kuwait, Malaysia, Qatar, Saudi Arabia, Singapore, South Africa and the United Arab Emirates. During 2000-2010, the major countries of origin of migrants are China, India, Indonesia, Mexico and the Philippines. Pakistan and Iran also have high negative net migration, partly as a result of the repatriation of Afghani refugees.

International migration is the component of population change most difficult to define, measure and estimate reliably. Thus, the quality and quantity of the data used in the estimation and projection of net migration varies considerably by country. Furthermore, the movement of people across international boundaries, which is very often a response to changing socio-economic, political and environmental forces, is subject to a great deal of volatility. Refugee movements, for instance, may involve large numbers of people moving across boundaries in a short time. For these reasons, projections of future international migration levels are the least robust part of current population projections and reflect mainly a continuation of recent levels of net migration.

## V. ASSUMPTIONS UNDERLYING THE 2004 REVISION

To project population until 2050, the United Nations Population Division applies assumptions regarding future trends in fertility, mortality, and migration. Because future trends cannot be known with certainty, a number of projection variants are produced. The Highlights focus on the medium variant of the *2004 Revision*. The assumptions of the medium variant are outlined in detail in section A of this chapter.

The *2004 Revision* includes five additional variants: the high, low, constant-fertility, constant-mortality, and zero-migration variants. The assumptions that differentiate these variants from the medium variant are described in section B. Detailed results of these variants will be made available in forthcoming publications.

The future population of each country is projected from an estimated population for 1 July 2005. Because actual population data for 2005 are not yet available, the 2005 estimate is based upon the most recent population data available for each country, derived usually from a census or population register, updated to 2005 using all available data on fertility, mortality and international migration. In cases where very recent data are not available, estimated demographic trends are short term projections from the most recent available data. Population data from all sources are evaluated for completeness, accuracy and consistency, and adjusted where necessary.<sup>8</sup>

### A. ASSUMPTIONS OF THE MEDIUM VARIANT

#### 1. Fertility assumptions: Convergence toward total fertility below replacement

Total fertility in all countries is assumed to converge eventually toward a level of 1.85 children per woman. However, not all countries reach this level during the projection period, that is, by 2050. The basic principle of fertility projection is the same for all countries, but projection procedures are slightly different depending on whether countries had a total fertility above or below 1.85 children per woman in 2000-2005.

For those countries with total fertility above 1.85 children per woman, fertility is assumed to follow a path derived from models of fertility decline established by the United Nations Population Division on the basis of the past experience of all countries with declining fertility during 1950-2000. The models relate the level of total fertility during a period to the average expected decline in total fertility during the next period. If the total fertility projected by a model for a country falls to 1.85 children per woman before 2050, total fertility is held constant at that level for the remainder of the projection period (that is, until 2050).

In all cases, the projected fertility paths yielded by the models are checked against recent trends in fertility for each country. When a country's recent fertility trends deviate considerably from those consistent with the models, fertility is projected over an initial period of 5 or 10 years in such a way that it follows recent experience. The model projection takes over after that transition period. For instance, in countries where fertility has stalled or where there is no evidence of fertility decline, fertility is projected to remain constant for several more years before a declining path sets in.

For countries where total fertility was below 1.85 children per woman in 2000-2005, it is assumed that over the first 5 or 10 years of the projection period fertility will follow the recently observed trends in each country. After that transition period, fertility is assumed to increase

---

<sup>8</sup> For a general description of the procedures used in revising estimates of population dynamics, see *World Population Prospects: The 2002 Revision, Volume III: Analytical Report*, pp. 180-182.

linearly at a rate of 0.07 children per woman per quinquennium. Thus, countries whose fertility is currently very low need not reach a level of 1.85 children per woman by 2050.

## *2. Mortality assumptions: Increasing life expectancy except when affected by HIV/AIDS*

### *a. Normal mortality assumptions*

Mortality is projected on the basis of models of change of life expectancy produced by the United Nations Population Division. These models produce smaller gains the higher the life expectancy already reached. The selection of a model for each country is based on recent trends in life expectancy by sex. For countries highly affected by the HIV/AIDS epidemic, the model incorporating a slow pace of mortality decline has generally been used to project the reduction of general mortality risks not related to HIV/AIDS.

### *b. The impact of HIV/AIDS on mortality*

For the 60 countries highly affected by the HIV/AIDS epidemic (listed in table VIII.21), estimates of the impact of HIV/AIDS are made by explicitly modelling the course of the epidemic and by projecting the yearly incidence of HIV infection. The model developed by the UNAIDS Reference Group on Estimates, Modelling and Projections<sup>9</sup> is used to fit past estimates of HIV prevalence provided by UNAIDS so as to derive the parameters determining the past dynamics of the epidemic. For most countries, the model is fitted assuming that the relevant parameters have remained constant in the past. Beginning in 2005, the parameter PHI, which reflects the rate of recruitment of new individuals into the high-risk or susceptible group, is projected to decline by half every thirty years. The parameter R, which represents the force of infection, is projected to decline in the same manner. The reduction in R reflects the assumption that changes in behaviour among those subject to the risk of infection, along with increases in access to treatment for those infected, will reduce the chances of transmitting the virus. The rate of mother-to-child transmission is projected to decline at varying rates, depending on each country's progress in increasing access to treatment. In addition, the component of the Reference Group model relative to the survivorship of infected children has been updated: in the *2004 Revision* it is assumed that 50 per cent of children infected through mother-to-child transmission will survive to age two.

The *2004 Revision* incorporates for the first time a longer survival for persons receiving treatment with highly active antiretroviral therapy (ART). The proportion of the HIV-positive population receiving treatment in each country is consistent with estimates prepared by the World Health Organization for the end of 2004<sup>10</sup>. Coverage is projected to reach between 40 per cent and 85 per cent by 2015, depending on the current level of coverage. It is assumed that, on average, annual survival probabilities increase to at least 80 per cent for individuals receiving ART. Under this assumption, mean survival from the initiation of therapy is 3.1 years (median 4.5 years). In contrast, in the absence of treatment mean survival after progression to AIDS is assumed to be just one year.

## *3. International migration assumptions*

The future path of international migration is set on the basis of past international migration estimates and an assessment of the policy stance of countries with regard to future international migration flows.

<sup>10</sup> World Health Organization. "3 by 5" Progress Report, December 2004/WHO and UNAIDS.

## B. PROJECTION VARIANTS

The *2004 Revision* includes five projection variants in addition to the medium variant. Three variants—high, low and constant-fertility—differ from the medium variant only in the projected level of total fertility. In the high variant, total fertility is projected to remain 0.5 children above the total fertility in the medium variant over most of the projection period. For example, countries reaching a total fertility of 1.85 in the medium variant reach a total fertility of 2.35 in the high variant. In the low variant, total fertility is projected to remain 0.5 children below the total fertility in the medium variant. In the constant-fertility variant, total fertility remains constant at the level estimated for 2000-2005.

A constant-mortality variant and a zero-migration variant have also been prepared. They both have the same fertility assumption as the medium variant. Furthermore, the constant-mortality variant has the same international migration assumption as the medium variant. Consequently, the results of the constant-mortality variant can be compared with those of the medium variant to assess the effect that changing mortality has on other demographic parameters. Similarly, the zero-migration variant differs from the medium variant only with respect to the underlying assumption regarding international migration. Therefore, the zero-migration variant allows an assessment of the effect that non-zero migration has on other demographic parameters.

## C. METHODOLOGICAL CHANGES MADE FOR THE *2004 REVISION*

- In the medium variant, the fertility of countries with a total fertility below 1.85 children per woman in 2000-2005 is projected first by continuing recent trends and then by increasing fertility linearly at a rate of 0.07 children per woman per quinquennium. These countries do not necessarily reach a level of 1.85 children per woman by 2050.
- In the *2004 Revision*, additional models of mortality change have been used to capture the diversity of historical experience in the rise of life expectancy. Specifically, very slow and very fast models of change have been developed and added to the previously existing slow, medium and fast models.
- The impact of HIV/AIDS on mortality is modelled explicitly for all countries that had adult HIV prevalence of one per cent or greater in 2003.
- Treatment with antiretroviral therapy is explicitly incorporated into the projection of HIV/AIDS for affected countries. In addition, the rate of mother-to-child transmission of HIV is projected to decline at a rate consistent with projected progress in expanding access to treatment.

## VI. DEFINITION OF MAJOR AREAS AND REGIONS

### Africa

<i>Eastern Africa</i>	<i>Middle Africa</i>	<i>Northern Africa</i>	<i>Western Africa</i>
Burundi	Angola	Algeria	Benin
Comoros	Cameroon	Egypt	Burkina Faso

## VII. ORDERING THE DATA ON CD-ROM

The results of the *2004 Revision* will be issued in a series of publications entitled *World Population Prospects: The 2004 Revision* that will consist of three volumes: Volume I: *Comprehensive Tables*, Volume II: *The Sex and Age Distribution of Populations*, and Volume III: *Analytical Report*. In addition, a chart entitled *World Population 2004* will be issued.

Highlights from the *2004 Revision* have been posted on the Population Division's web site ([www.unpopulation.org](http://www.unpopulation.org)). In addition, the data of the *2004 Revision* will be released in digital form. The list of data sets produced in digital form and an order form for their purchase will be posted on the Population Division's web site.

## VIII. ANNEX TABLES

TABLE VIII.1. TOTAL POPULATION BY SEX AND SEX RATIO, BY COUNTRY, 2005 (MEDIUM VARIANT)

Country or area	Population (thousands)			Sex ratio (males per 100 females)
	Total	Male	Female	
World.....	6 464 750	3 248 919	3 215 831	101
Afghanistan.....	29 863	15 404	14 459	107
Albania.....	3 130	1 552	1 578	98
Algeria.....	32 854	16 577	16 277	102

<sup>1</sup> The median age of the population for the world makes allowance for the median age of countries and areas with less than 100,000 inhabitants in 2000.

<sup>2</sup> Including Christmas Islands, Cocos (Keeling) Islands and Norfolk Island.

<sup>3</sup> As of July 1st 1997, Hong Kong became a Special Administrative Region (SAR) of China.

<sup>4</sup> As of December 20th 1999, Macao became a Special Administrative Region (SAR) of China.

<sup>5</sup> Including Agalega, Rodrigues and St. Brandon.

<sup>6</sup> The former Yugoslav Republic of Macedonia.

\* Countries or areas with 100,000 inhabitants or more in 2000.

TABLE VIII.13. TEN COUNTRIES OR AREAS WITH HIGHEST AND TEN COUNTRIES OR AREAS WITH THE LOWEST TOTAL FERTILITY, 1970-1975, 2000-2005 AND 2045-2050 (MEDIUM VARIANT)

1970-1975			2000-2005			2045-2050		
Rank	Country or area	Total fertility	Rank	Country or area	Total fertility	Rank	Country or area	Total fertility
<i>A. Highest fertility</i>

<sup>1</sup> The total fertility for the world makes allowance for the total fertility of countries and areas with less than 100,000 inhabitants in 2000.

<sup>2</sup> Including Christmas Islands, Cocos (Keeling) Islands and Norfolk Island.

<sup>3</sup> As of July 1st 1997, Hong Kong became a Special Administrative Region (SAR) of China.

<sup>4</sup> As of December 20th 1999, Macao became a Special Administrative Region (SAR) of China.

<sup>5</sup> Including Agalega, Rodrigues and St. Brandon.

<sup>6</sup> The former Yugoslav Republic of Macedonia.

\* Countries or areas with 100,000 inhabitants or more in 2000.

TABLE VIII.17. TEN COUNTRIES OR AREAS WITH THE HIGHEST AND TEN COUNTRIES OR AREAS WITH THE LOWEST LIFE EXPECTANCY AT BIRTH, 2000-2005 AND 2045-2050

2000-2005			2045-2050
