## NOTE

The designations employed and the presentation of material in this publication do not imply the expression of any opinion whatsoever on the part of the Secretariat of the United Nations concerning the legal status of any country, territory, city or area or of its authorities, or concerning the delimitation of its frontiers or boundaries.

Where the designation "country or area" appears in the headings of tables, it covers countries, territories, cities or areas.

In some tables, the designations "developed" and "developing" economies are intended for statistical convenience and do not necessarily express a judgement about the stage reached by a particular country or area in the development process.

In the present publication, references to "China" are to be understood in the light of General Assembly resolution 2758 (XXVI) of 25 October 1971.

The views expressed in signed papers are those of the individual authors and do not imply the expression of any opinion on the part of the United Nations Secretariat.

Symbols of United Nations documents are composed of capital letters combined with figures. Mention of such a symbol indicates a reference to a United Nations document.

## PREFACE

The World Population Conference held at Bucharest, Romania, from 19 to 30 August 1974<sup>1</sup> was the third in a series of population conferences convened under the auspices of the United Nations. The first two conferences, which took place in Rome in 1954 and in Belgrade in 1965, were purely professional in nature. The Bucharest Conference, convened under Economic and Social Council resolution 1484 (XLVIII) of 3 April 1970, reflected the increasing concern with population questions in the world today and was a global conference of Governments which devoted its attention to the national and international population policies and action programmes needed to promote human welfare and development.

Four United Nations symposia on population questions were held prior to the Conference, in which experts addressed themselves to the substantive aspects of the complex interrelationships between population and the multiplicity of socio-economic and other factors which affect it and are in turn affected by it. These were: the Symposium on Population and Development (Cairo, 4-14 June 1973); the Symposium on Population and the Family (Honolulu, 6-15 August 1973); the Symposium on Population, Resources and the Environment (Stockholm, 26 September-3 October 1973); and the Symposium on Population and Human Rights (Amsterdam, 21-29 January 1974). The reports of the symposia, which were before the Conference, form annexes I to IV to volume II of the present publication.

It will be noted that the topics of the four symposia went beyond what used to be called "formal demography". This was necessary in view of the crucial importance of population in development and also of the mutual relationship between man and his environment, a relationship which involves not only social and economic factors but cultural factors, family structure and human rights, as well as the physical environment.

---

<sup>1</sup>The *Report of the World Population Conference* will be issued as a United Nations publication under the symbol E/CONF.60/19.

It was also necessary to supplement the material of the four symposia in order to cover other aspects of population. For this purpose, background papers were prepared covering a variety of topics ranging from demographic analysis to research and training, biomedical aspects, ecological aspects, population policies and family planning. These papers were made available to Governments prior to the Conference.

Digests of all of these papers—documents and reports of the symposia as well as background papers—were prepared in order to provide the participants in the Conference with concise summaries, corresponding to four of the items on the agenda of the Conference, namely, "Recent population trends and future prospects"; "Population change and economic and social development"; "Population, resources and environment"; and "Population and the family".

In continuation of the tradition of publishing the papers of the United Nations world population conferences, the United Nations presents in *The Population Debate: Dimensions and Perspectives* all the substantive documents that were prepared for the World Population Conference, 1974, including the main conference documents and the background papers, as well as the documents and the reports of the four symposia. In addition, part one of volume I gives the text of the World Population Plan of Action adopted by the Conference.

It is hoped that this collection of papers will, *inter alia*, serve the needs of the large number of professionals—not demographers only but also economists, sociologists, ecologists, medical scientists and others—whose interests cover population questions but who were unable to attend the Conference.

Acknowledgements are due to the large number of consultants and various United Nations offices and specialized agencies which helped the Population Division of the Department of Economic and Social Affairs of the United Nations Secretariat in preparing the documents, as well as to the United Nations Fund for Population Activities, whose grant made this publication possible.

## COMPOSITION OF THIS PUBLICATION

The papers of the World Population Conference, 1974, are published under the title *The Population Debate: Dimensions and Perspectives*. They are arranged in two volumes under the following headings:

### *Volume I*

- Part One. The population debate: a digest
- Part Two. World demographic trends and prospects
- Part Three. Demographic data collection, research and training
- Part Four. Population and development

### *Volume II*

- Part Five. Population, resources and the environment
- Part Six. Population and the family
- Part Seven. Population and human rights
- Part Eight. Family planning
- Part Nine. Population policies and programmes
- Annex I. Report of the Symposium on Population and Development
- Annex II. Report of the Symposium on Population, Resources and Environment
- Annex III. Report of the Symposium on Population and the Family
- Annex IV. Report of the Symposium on Population and Human Rights

The papers are reproduced in their original languages. They have been edited and consolidated in accordance with United Nations practice and requirements.

All general cross references to papers contained in these volumes are given in the following form:

Name of author, title of paper, *Population Debate*, vol. I or vol. II, part one, two, . . . . Specific references are to paragraph numbers, tables or figures in the paper cited.

## CONTENTS

### Volume II

*EXPLANATORY NOTES*

The following symbols have been used in the tables throughout the report:

Three dots (...) indicate that data are not available or are not separately reported

A dash (—) indicates that the amount is nil or negligible

A blank in a table indicates that the item is not applicable

A minus sign (–) indicates a deficit or decrease, except as indicated

A full stop (.) is used to indicate decimals

A comma (,) is used to distinguish thousands and millions

A slash (/) indicates a crop year or financial year; e.g., 1970/71

Use of a hyphen (-) between dates representing years, e.g., 1971-1973, signifies the full period involved, including the beginning and end years.

Reference to "tons" indicates metric tons, and to "dollars" (\$) United States dollars, unless otherwise stated.

**Part Five**

**POPULATION, RESOURCES AND THE ENVIRONMENT**

## WILL THE EARTH'S LAND AND WATER RESOURCES BE SUFFICIENT FOR FUTURE POPULATIONS? \*

*Roger Revelle* \*\*

1. Human beings use both water and land for many purposes, but primarily for food production, that is, the transformation of matter and energy into a form that can be utilized for the growth and replacement of human tissue and the supplying of energy for human metabolism. Land is the primary resource required for food production, because of the dispersed nature of solar energy and of the low efficiency of photosynthetic conversion of solar energy into human food energy.

2. With a high level of agricultural technology, such as that used in growing corn in Iowa (United States of America), photosynthesis from a human standpoint is about 0.4 per cent efficient, that is, the food energy contained in the humanly edible portion of the crop is about 0.4 per cent of the solar energy received on the planted area during the growing season.

3. On average, the amount of solar energy received is  $4.5 \times 10^7$  kilocalories/hectare/day, and the energy content of the food produced in an Iowa corn field is  $4.5 \times 10^7 \times 0.004 = 1.8 \times 10^5$  kilocalories/hectare/day (1 kcal is the amount of heat required to raise the temperature of 1 kg of water  $1^\circ$  centigrade). Since only one crop is grown, with a growing season of about 4 months, this food energy must be divided by 3 to give the average daily production throughout the year:  $1.8 \times 10^5 \times \frac{1}{3} = 6 \times 10^4$  kilocalories/hectare/day. A nearly minimum subsistence diet for human beings is about 2,500 kilocalories/person/day (the amount of heat energy which will raise the temperature of 2.5 tons of water  $1^\circ$  centigrade.) Hence, the food energy required by 24 human beings can be provided from 1 hectare at a level of agricultural technology (and of purchased inputs, such as irrigation water, chemical fertilizers, high-yielding seeds, plant protection, farm tools and farm machinery) equivalent to that of corn farmers in Iowa. In terms of weight, the average Iowa corn crop is 250 bushels (14,000 lb) or about 6.4 metric tons ( $6.4 \times 10^6$  grams) per hectare. Each gram of corn contains 3.5 kcal of food energy, and  $6.4 \times 10^6$  grams/hectare  $\times$  3.5 kilocalories/gram  $\times$  1/365 days =  $6.2 \times 10^4$  kilocalories/hectare/day, which checks the previous calculation.

Each person requires the equivalent of 260 kg or about 570 lb of corn per year to meet his energy requirements.

4. For the world as a whole, at the current time, 1.4 thousand million hectares are cultivated to provide the food, fibres and other agricultural products needed by 3.5 thousand million human beings. There is 1 hectare of farm land for every 2.5 living persons. Several reasons explain why the actual cultivated land per person is nearly 10 times this calculated minimum:

(a) The land actually harvested during any particular year is from about one half to two thirds of the total cultivated land. The remainder is in temporary fallow and temporary meadows for mowing or pasture, or is not cropped for some other reason. When chemical fertilizers are not used, much farm land must lie fallow for a year or more to recover fertility;

(b) About 10 per cent of the cropped area is devoted to raising non-food crops, such as cotton, tobacco, rubber, coffee, tea and jute;

(c) Another large fraction is needed to produce food for livestock. Some of the livestock are used in cultivating the farms. The products from the remainder, including butter, eggs, milk and meat, are eaten by human beings. Livestock are only 10-15 per cent efficient, that is, they use from 7 to 10 times as much food energy as the energy contained in their edible products;

(d) From 10 to 20 per cent of the food crops are destroyed by pests, and a small percentage is required for seed;

(e) The principal cause is the low level of agricultural technology in most of the world. Instead of 6.4 metric tons per cropped hectare, the average Indian or Pakistani farmer produces only a little more than a ton of wheat or rice.

### HOW MUCH POTENTIALLY ARABLE LAND EXISTS ON THE EARTH?

5. Large areas of the earth's surface are not now cultivated, but could be if farmers and the necessary capital for development were available. In appraising the total quantity of arable land and its potential for food production, there are four factors to be considered: the area of land that could be cultivated; the quality of this land; the total water-supply available for irrigation; and the geographical distribution of currently

\* The original text of this paper (E/CONF.60/SYM.III/13/Rev.1) was submitted to the Symposium on Population, Resources and the Environment, Stockholm, 26 September-5 October 1973.

\*\* Harvard Center for Population Studies, Cambridge, Massachusetts, United States of America.

uncultivated, but potentially arable, land in relation to the geographical distribution of the world's population.

6. The area of potentially arable land is limited by:

(a) The climate, meaning that the land must be frost-free during the growing season;

(b) The physical characteristics of the land surface and the top 2 or 3 feet of earth material beneath the surface. (This material is called "soil" when it consists of more or less loose aggregates of particles.) These characteristics are:

(i) Permeability to water and to plant roots. The soil is the medium or substrate that holds the plant roots, and the roots must be able to extract water and plant nutrients from the "soil solution", the liquid existing in the interstices between solid particles. At the same time, it must be possible for water to pass through the soil and be drained off, carrying unwanted salts away in solution;

(ii) Water and nutrient-holding capacity. If the soil is too sandy or consists mainly of iron and aluminium hydroxides it will not retain water and plant nutrients will be washed out of it before they can be utilized by the crops;

(iii) The soil must be neither too acid nor too alkaline. Excessive acidity can usually be alleviated by adding lime, and alkalinity by washing the soil if drainage is available;

(iv) The surface must not be too steeply sloping or irregular;

(v) The soil must not be too rocky;

(c) The water-supply must be available during the growing season in amounts approximately equal to or greater than evaporation from the soil and transpiration from the plants.

#### *Magnitude of climatic limitations*

7. The land surface of the earth, outside the ice-covered areas of Antarctica and Greenland, contains 13 thousand million hectares. Of this total area, 1.9 thousand million hectares are non-arable, because temperatures below freezing occur during 9 or more months of the year. In an additional 2.6 thousand million hectares, there are less than 3 months of the year in which available moisture, either from rain and snow or from water stored in the soil, equals or exceeds evapotranspiration from plants and soil, and there are no feasible sources of irrigation water. Climate alone, therefore, limits the area of potentially arable land to 8.5 thousand million hectares.

#### *Limitations due to physical character of the land surface*

8. The following land and soil types, which overlap with the climatic limitations described above, contain large areas of non-arable land:

<i>Land or soil type</i>	<i>Non-arable area (thousand million hectares)</i>	<i>Reason for being non-arable</i>
Tundra	0.5	Too cold
Desert	1.9	Too dry, or too stony, rough and hard
Lithosol (rocky)	2.6	Too little soil; mostly rock
Regosol (sandy)	0.7	Too rough, unstable, and coarse-grained
Latosol (lateritic)	1.4	Becomes hard and impermeable after drying
Podsol (forest soils)	1.6	Too steeply sloping, thin, stony, or cold
All others	1.3	Too cold, undrainable, rough, thin, rocky, or steeply sloping
	10.0	

9. The remaining 3.2 thousand million hectares are arable. This is 24 per cent. of the land area of the earth, about 2.3 times the currently "cultivated" area, and more than 3 times the area actually harvested in any given year.

#### *Potential gross cropped area*

10. Table 1 shows the total potentially arable land on each continent and the potential gross cropped area, that is, the sum of potentially arable areas multiplied by the number of four-month growing season crops that could be grown in each area, with and without irrigation. Without irrigation, three crops could be grown on 5 million km<sup>2</sup> in the humid tropics, and two crops on 6 million km<sup>2</sup> in subhumid regions. One crop

could be grown without irrigation on 17 million km<sup>2</sup>. Thus, the potential gross cropped area (the cultivated areas times the number of crops), without irrigation, is 45 million km<sup>2</sup>. If enough water were available for irrigation, the gross cropped area could be as much as 72 million km<sup>2</sup>. Irrigation is necessary to grow even one crop on 3 million km<sup>2</sup> of potentially arable land.<sup>1</sup>

#### *Potential water-supply*

11. The total amount of rain and snow falling on the earth each year is about 470,000 km<sup>3</sup>; 370,000

<sup>1</sup> Roger Revelle and others, "Water and land", in United States of America, President's Science Advisory Committee, *The World Food Problem*, report of the Panel on the World Food Supply (Washington, D.C.: Government Printing Office, 1967), vol. II, chap. 7, pp. 405-469.

TABLE I. PROJECTIONS FOR LAND AND WATER DEVELOPMENT IN CERTAIN DEVELOPING REGIONS, 1962-1985

	Africa south of Sahara	Asia and Far East	Latin America	Near East and North-West Africa	Total
1. Cultivated area					
In 1962 (millions of hectares)	152	211	130	70	563
In 1985 (millions of hectares)	189	223	169	78	659
Increase 1962-1985 (millions of hectares)	37	12	39	8	96
Increase 1962-1985 (percentage)	24	6	30	12	17
2. Gross cropped area					
In 1962 (millions of hectares)	64	211	71	39	385
In 1985 (millions of hectares)	99	269	102	50	520
Increase 1962-1985 (millions of hectares)	35	58	31	11	135
Increase 1962-1985 (percentage)	55	27	44	28	35
3. Gross cropped irrigated area					
In 1962 (millions of hectares)	1.1	49.5	8.2	12.8	71.6
In 1985 (millions of hectares)	2.1	102.7	16.2	17.8	138.8
Increase 1962-1985 (millions of hectares)	1.1	53.2	8.0	5.0	67.2
Increase 1962-1985 (percentage)	100	107	98	39	94
4. Costs of development (millions of 1970 dollars)					
Irrigation	893	23,095	7,259	4,944	36,191
Drainage and flood control	59	2,008	390	325	2,783
Development of new land not associated with irrigation	208	1,974	4,693	1,141	8,016
Total	1,150	27,077	12,342	7,547	48,116
5. Gross value of crop production					
1962 (dollars per hectare)	35.8	105.0	68.2	51.8	71.2
1985 (dollars per hectare)	58.4	237.1	105.1	103.0	136.1
Increase (percentage)	63	126	54	99	91
Total 1962 (10 <sup>9</sup> dollars)	5.44	22.16	8.87	3.63	40.09
Total 1985 (10 <sup>9</sup> dollars)	11.04	52.87	17.76	8.03	89.69
Increase 1962-1985 (10 <sup>9</sup> dollars)	5.60	30.71	8.89	4.40	49.60
Increase 1962-1985 (percentage)	103	139	100	121	124
6. Population					
1962 (millions)	201	833	225	135	1,394
1985 (millions)	357	1,471	433	254	2,515
Increase 1962-1985 (percentage)	78	77	92	88	80

SOURCE: Food and Agriculture Organization of the United Nations, *Provisional Indicative World Plan for Agricultural Development* (Rome, 1970), vol. I, chap. 2, pp. 32-70.

km<sup>3</sup> on the ocean and 100,000 km<sup>3</sup> on the land. Over the ocean, 9 per cent more water evaporates than falls back as rain. This is balanced by an equal excess of precipitation over evaporation on land. Consequently, the volume of water carried to the sea by rivers and coastal springs (and in small part by glaciers) is close to 32,000 km<sup>3</sup> per annum. About 18,000 km<sup>3</sup> are carried by 69 major river systems from a drainage area of 56 million square kilometres.<sup>2</sup> Somewhat less than half the run-off of liquid water from the land to the ocean is carried by thousands of small rivers flowing across coastal plains or islands. The area drained is about 44 million km<sup>2</sup>, but part of this is desert with virtually no run-off.

<sup>2</sup> R. Reville, P. Rogers and H. Thomas, "Some international aspects of water resource development", in United States of America, State Department, *International Problems of Science and Technology* (Washington, D.C., 1968).

12. Inland seas, lakes, or *playas* receive the drainage from 32 million km<sup>2</sup>. This includes most of the earth's 24 million km<sup>2</sup> of desert and also such relatively well-watered areas as the basins of the Volga, Ural, Amu Darya and Syr Darya rivers, which transport several hundred thousand cubic kilometres of water each year into the Caspian and Aral seas.

13. Irrigation agriculture represents man's principal deliberate use of water; currently, however, it takes little of the available supply. A little over 1,000 km<sup>3</sup>—less than 4 per cent of the total river flow—is used to irrigate 160 million hectares or about 1 per cent of the land area of the earth. About 10 times this quantity of rainfall and snow-fall is evaporated and transpired each year from the remaining 1,250,000 hectares of the earth's cultivated lands and helps to grow food and fibre. Most river waters flow to the sea almost unused by man, and more than half of the water evaporating from the continents, particularly that part of the evapo-

ration taking place in the wet rain forests and semi-humid savannahs of the tropics, plays little part in human life.

14. The potential for irrigation development is, thus, very large, but it is limited by the uneven distribution of river run-off between the different continents and within different climatic zones on each continent. About a third of the total run-off comes from South America, with less than 15 per cent of the earth's land area, while Africa, which contains 23 per cent of the land, yields only 12 per cent of the run-off. Run-off from south-west Asia, North Africa, Mexico, the south-western United States, temperate South America and Australia is less than 5 per cent of the total, yet these regions contain 25 per cent of the land area (table 2).

15. As a result of the uneven distribution of run-off, no more than 30 per cent of the land that is potentially arable only with irrigation can actually be irrigated,

and the potential increase of gross cropped area through irrigation development is limited to 1,110 million hectares. The total potentially arable land is, thereby, reduced to 2,925 million hectares and the potential gross cropped area to 5,562 million hectares (table 3). The distribution of potentially arable and gross cropped areas by continent is shown in table 4.

#### SOME OF THE OBSTACLES

16. What are the obstacles to the potential expansion of the earth's cultivated area? These obstacles are of several kinds, described below.

#### *New technology needed for the humid tropics*

17. Some 1.5 thousand million hectares of the potential cropped area lie in the humid tropics, where rainfall is more or less continuous throughout the year.

TABLE 2. ESTIMATED RIVER RUN-OFF AND IRRIGATION POTENTIAL, BY CONTINENT

Continent	Total area (million km <sup>2</sup> )	Major drainage basins (million km <sup>2</sup> )	Major river discharge (km <sup>3</sup> )	Estimated total discharge (km <sup>3</sup> )	Needed for full irrigation (km <sup>3</sup> )	Potential gross cropped irrigated area with full irrigation (million km <sup>2</sup> )	Potential gross crop irrigated area with available water (million km <sup>2</sup> )

TABLE 3. WORLD SUMMARY OF POTENTIAL NET AND GROSS CROPPED AREAS  
(Millions of hectares)

	<i>Current gross cropped area<sup>a</sup></i>	
(1)	Land potentially arable without irrigation	2,820
(2)	Land potentially arable only with irrigation	330
(3) = (1) + (2)	Total potentially arable (net cropped) land	3,150
(4)	Land potentially arable without irrigation outside humid tropics (technology must be developed for humid tropics)	2,320
(5)	Land potentially arable only with irrigation where sufficient water is available	107
(6) = (4) + (5)	Total potentially arable (net cropped) land outside humid tropics with sufficient water from precipitation or irrigation to grow at least one crop	2,427
(7)	Total irrigable area (land where at least one crop could be grown under irrigation, and sufficient water could be made available for this purpose)	1,027
(8)	Net "cultivated" area in 1964 (only about 65% cropped)	1,380
(9)	Net irrigated area in 1964	162
	<i>Potential gross cropped area<sup>a</sup></i>	
(10)	Potential gross cropped area without irrigation	4,450
(11)	Potential gross cropped irrigated area with full irrigation (no water limitation)	2,730
(12) = (10) + (11)	Potential gross cropped area with full irrigation (no water limitation)	7,180
(13)	Potential gross cropped irrigated area with available water	1,112
(14)	Potential gross cropped non-irrigated area outside humid tropics (technology must be developed for humid tropics)	2,950
(15) = (13) + (14)	Potential gross cropped irrigated and non-irrigated area with present technology and available water	4,062

SOURCE: Compiled from Food and Agriculture Organization of the United Nations, *Production Yearbook No. 18, 1964*, tables 1-3.

<sup>a</sup>Gross cropped area is the cultivated area multiplied by the number of crops harvested during the year. This number expressed as a percentage is called the intensity of cultivation. For example, if two crops are harvested during the year, the intensity of cultivation is 200 per cent. Potential gross cropped area is the sum of arable land areas multiplied by the number of four-month growing season crops that could be harvested from each area. For example, an area of 1 million hectares

(1 mha), in which the air temperature remains above freezing and available water (including soil moisture) from either precipitation or irrigation exceeds potential evapo-transpiration at all times during the year, would be a potential gross cropped area of 3 million hectares. In estimating water requirements for full irrigation, it was assumed that each four-month crop would consume by evapo-transpiration 0.67 metres of irrigation water and that there would be a 50 per cent water loss in the irrigation system. Thus, each gross cropped hectare would require  $1.33 \times 10^4 \text{ m}^3$  of water and each million square kilometres ( $10^8$  hectares) would require  $1,333 \times 10^9 \text{ m}^3$ .

culations from table 2.

<sup>a</sup>Numbers in brackets are areas outside humid tropics with available water; those in parentheses are areas outside the humid tropics.

No technology exists today for intensive cultivation of these lands for food production, because of the highly leached nature of the soils and their consequent inability to retain plant nutrients. Except for the island of Java and a few similar places, with very deep, recently formed volcanic soils, and for certain tree crops in other areas, farmers in the humid tropics must still practise the ancient technique of "slash-and-burn" agriculture. A new technology for intensive food production may require genetic development of food-producing trees, which can retain and recycle fertilizers in a carpet of organic matter on top of the soil.

18. The available evidence, especially from the impressive research in Central Africa, supports the prospect that, with the appropriate technological development, the humid tropics could have tremendous potential for food production. The Belgians, for example, before suspending their research in the Congo, had developed an oil-palm which, when properly grown, yielded about 4,000 kg per hectare, whereas the ordinary palm yielded about 500 kg per hectare. In the humid Amazon Valley, peppers have been grown successfully by several colonies of Japanese immigrants for at least 20 years.<sup>4</sup>

#### *Poor quality of much potentially arable land*

19. The savannahs of South America and the broad belt that extends from east to west across Africa just south of the Sahara contain large areas of reddish-brown and yellowish-brown lateritic soils and latosols. These are among the most severely weathered and leached soils of the world.<sup>4</sup> Their meagre supply of plant nutrients is barely enough to support cropping for from 2 to 4 years, after which long periods—from 6 to 12 years or more of fallow—are necessary to restore their limited productivity. These soils are almost universally low in phosphorous and they have the unfavourable tendency of "fixing" phosphorous fertilizer and, thereby, making it unavailable to plants. On the other hand, many of them are permeable to both air and water, easily penetrated by roots to great depth, easy to keep in good tilth and have at least moderate water-holding capacity. With adequate irrigation water, chemical fertilizers and soil conditioners these soils could be made highly productive of a wide variety of food crops. In the northern part of the sub-Saharan region, large areas of regosols exist—sands which are highly susceptible to blowing and have such a low water-holding capacity that their potential for crop production is severely limited.

20. In other potentially arable lands, considerable soil improvement, e.g., by the addition of large quantities of lime, is necessary.

#### *Large capital investment required*

21. In general, any major extension of the earth's cultivated area, even for subsistence agriculture, would

require a huge capital investment of the order of from \$500 to \$1,000 per hectare.<sup>5</sup> The cost of putting all the potentially arable land outside the humid tropics under cultivation would be from 500 thousand million to 1,000 thousand million dollars. The higher figure is about equal to the annual gross national product of the United States of America and twice that of all the less developed countries.

#### *Uneven distribution of population and potentially arable land*

22. Of the world's peoples, 70 per cent live in Asia and Europe, where nearly all the arable land is already cultivated, and the remainder can be brought under the plough only at the expense of large-scale irrigation development. The potential for increasing the net cultivated area is also relatively small in the Union of Soviet Socialist Republics. Most of the uncultivated, but arable, land is in the more sparsely populated continents.

23. In table 5, the quantity of potentially arable land outside the humid tropics, in which sufficient water is or could be made available on each continent, is compared with the currently cultivated area. Cultivated area means the lands designated by the Food and Agriculture Organization of the United Nations (FAO) as arable land and land under permanent crops, including land under crops, temporary fallow, temporary meadows for mowing and pastures, market and kitchen gardens, fruit-trees, vines, shrubs and rubber plantations. Within this designation, there are said to be wide variations within reporting countries. The area actually harvested during any particular year is from about one half to two thirds of the total cultivated land.

24. Human diets in Asia are barely sufficient today. If the Asiatic peoples are to obtain sufficient food in the future, it will be necessary to increase yields, that is, the weight of each crop per hectare of cultivated land, and, wherever possible, to grow two or three crops per year on each cultivated hectare. The climate in nearly all potentially arable, but currently uncultivated, land in Asia is so arid that even one four-month growing-season is impossible without irrigation, and water-supplies are inadequate for more than about 15 million hectares (table 4). Within the currently cultivated area, double or triple cropping will usually require extensive irrigation development.

25. The largest areas of potentially arable land are in Africa and South America, which, outside the relatively small continents of Europe and Australia, have the smallest cultivated acreage. As table 4 shows, in these two continents, counting the humid tropic areas, there are nearly 1,300 million hectares of potentially arable uncultivated land with sufficient water (not much less than the total currently cultivated area of the earth) and only 240 million hectares that are cultivated.

TABLE 5. POPULATION AND CULTIVATED LAND ON EACH CONTINENT, COMPARED WITH POTENTIALLY ARABLE LAND

Region	Estimated population (millions)		Arable land (millions of hectares)		Percentage of potential already cultivated	Cultivated area per person (hectares)	
	1965	1985	Potential	Cultivated		1965	1985 <sup>a</sup>
Africa	310	515	500	160	32	0.5	1.0
Asia	1,855	2,700	465	470 <sup>b</sup>	101	0.3	0.2
Australia and New Zealand	14	25	120	20	16	1.4	4.8
Europe	445	490	170	150	88	0.4	0.3
North America	255	330	450	240	53	0.9	1.4
South America	197	390	370	80	21	0.9	1.4
USSR	243	295	350	230	66	1.0	1.2
TOTAL	3,320	4,745	2,425	1,350	56	0.4	0.5

<sup>a</sup> Assuming all potentially arable land is cultivated.

<sup>b</sup> In Asia, some humid tropic land is cultivated (for example, in Java).

Outside the humid tropics, 630 million hectares with sufficient water remain uncultivated. The limiting factors in agricultural development in these continents are not natural resources, but economic, institutional and socio-political problems. In addition to potential land in Africa and South America, over 300 million hectares of potentially arable, but not cultivated, land exist in North America and Australia.

#### Necessity to improve level of agricultural technology

26. Raising the level of agricultural technology is essential to increasing the yields from cultivated land and to bringing many currently uncultivated areas under the plough. The basic requirement is creation of better conditions for market agriculture, as contrasted with subsistence agriculture, because higher agricultural technology depends upon the ability of the farmers and the food industry to purchase, and of society to produce, many "inputs", or factors of production from outside the farm. A high degree of industrialization and of governmental and other institutional development is required. At the Iowa level of technology, energy must be used from fossil fuels equal to about three fourths the food energy in the crops. <sup>6</sup> Table 6 shows how this energy is utilized.

27. On the average, the less developed countries now use about 400 kg of coal equivalent per person per year, corresponding to an annual use of 3 million kcal per person. Thus, to meet his dietary needs adequately with high agricultural technology, a person in a less developed country would need to use for food production about one third of all the energy available to him. In contrast, the average person in developed countries uses 14 times as much fossil fuel energy as that required to meet all his agricultural requirements, even though the high proportion of animal product in his diet means that he is consuming from 3

TABLE 6. ESTIMATED ENERGY CONSUMPTION FROM FOSSIL FUELS

(10<sup>6</sup> kilocalorie/ton of food-grains<sup>a</sup>).

	Energy consumption
(1) Irrigation water	0.78 <sup>b</sup>

(5) Farm tools and farm machinery	0.44
(6) Fuel for operating farm machinery	0.40
(7) Scientific knowledge required for improved practices	—
(8) Electricity	0.16
(9) Transportation facilities (roads and trucks)	0.04
(10) Crop drying	0.06
(11) Storage and marketing facilities	0.01
(12) Food-processing facilities (flour and sugar mills, food preservation plants etc.)	0.22
TOTAL	2.86

<sup>a</sup> One ton of food-grains contains 3.5 × 10<sup>6</sup> kilocalories.

<sup>b</sup> Assuming electric-powered pumps, 0.6 metre evapo-transpiration, water pumped from 20 metres, 50 per cent water-course and field losses.

<sup>c</sup> 130 kg of nitrogen, 34 kg of phosphorus, 70 kg of potassium per hectare.

to 4 times as many plant calories as the average person in a less developed country.

#### HOW MANY PEOPLE COULD BE FED?

28. Considering only currently available technology, the world areas of potentially arable net and gross cropped land outside the humid tropics are approximately 2,430 million and 4,060 million hectares; respectively.

29. About 10 per cent of the gross cropped area will continue to be needed to grow fibres, beverages and other non-food products.

30. With appropriate technology and sufficient purchased inputs of production (irrigation water, fertilizer,

<sup>6</sup> R. Revelle and others, *loc. cit.*; D. Pimental and others, *Corn, Food and the Energy Crisis* (Ithaca, New York, Cornell University, Department of Entomology and Section of Ecology and Systematics, 1973).

high-yielding seeds, plant protection, farm tools, farm machinery and farming practices based on scientific knowledge) equivalent to those used in Iowa corn-farming, the remaining 3,650 million gross cultivated hectares could be made to produce:

$$6 \times 10^4 \times 3.65 \times 10^9 \\ = 2.2 \times 10^{14} \text{ kilocalories per day}$$

31. Allowing 10 per cent of this amount for unavoidable losses, and another 3 per cent for seed, the remainder would be enough to provide a minimum subsistence diet of 2,500 kilocalories per day for 7.6 thousand million people.

32. To provide an adequate diet, including sufficient high-quality protein (protein with the balanced content of amino acids required by human beings and all other warm-blooded animals, except cattle and related ruminants) and "protective" foods, such as fruits and vegetables, the equivalent of from 4,000 to 5,000 kilocalories/person/day is desirable. The potential gross cropped area would be sufficient for from 38 thousand million to 48 thousand million people—from 10 to 13 times the current population of the earth.

#### POTENTIAL AND REALITY

##### *Expansion of cultivated area versus multiple cropping and raising of yields*

33. During the first 10 years after the Second World War, the net harvested acreage in Asia (excluding China) increased about 2 per cent per annum. After 1957-1958, however, the rate of increase was only about 1.4 per cent per annum. While the rate of population increase accelerated, the rate of increase of harvested areas declined. This situation may have been related in part to the very low level of expenditure on water resources development, less than \$2 per year per person, as well as to the relative scarcity of uncultivated land that could be cultivated.<sup>7</sup>

34. The rate of increase of cultivated areas was even lower in Africa than in Asia; it was higher in South America, averaging 3 per cent annually from 1950 to 1965 and nearly 4 per cent during the 1960s.<sup>8</sup> On a world-wide basis, if population growth were to be matched by increases in cultivated area, annual *per capita* expenditures on water and land development would have to increase from two to four times.

35. For the next 20 or 30 years, a combined strategy for the less developed countries of increasing both multiple cropping and total cultivated area, as well as yields from each gross cropped hectare, has been recommended by FAO.<sup>9</sup> Table 1 shows that with a total expenditure of 48 thousand million dollars, the gross value of crop production could be increased over all by 124 per cent with a 17 per cent growth in the

cultivated area and a 35 per cent growth in gross cropped area between 1962 and 1985, in four developing regions: Africa south of the Sahara; the Near East and North-west Africa; Asia and the Far East; and Latin America. China and other centrally planned economies were omitted from the study summarized in table 1; but, even so, it covered a 1962 population of 1,394 million people, 44 per cent of the world population. The population of the study region was estimated to rise to 2.5 million by 1985, an 80 per cent increase. Thus, the 124 per cent projected over-all increase in food production would be well ahead of population growth for the next 20 years.<sup>10</sup> Population and food supplies run a close race only in Latin America. In this regard, the FAO Provisional Indicative World Plan states:

"The correct degree of emphasis on expansion of the cultivated area versus higher productivity from existing areas in Latin America would seem to depend in great part on the rate at which food demand will rise. If income elasticities (for food) are low in some South American countries, as data at the disposal of FAO would seem to show, emphasis should be placed on a much faster growth of industrial goods and services than of food. The correct policy would then be to concentrate on modernization of agriculture through increased inputs and better techniques and a faster movement of the labour force out of agriculture to produce the goods and services in high demand. Forest-based industrialization can be developed so as to play a substantial role in bringing about the restructuring of the economy. A corollary is that investment in the non-agricultural sector must be sufficient to employ these people and produce these goods."<sup>11</sup>

##### *Conflicts in water use*

36. It has been tacitly assumed that all river run-off available for human use could be allocated to irrigation agriculture. But cities and their industries are also consumers of water. In India, for example, the Irrigation Commission<sup>12</sup> estimates that 17 per cent of the usable water will be needed for industrial and municipal use, leaving a total of 720 thousand million m<sup>3</sup> for irrigation (out of a total estimated annual river flow of 1,800 thousand million m<sup>3</sup> = 1,800 km<sup>3</sup> = 1.8 × 10<sup>12</sup> m<sup>3</sup>). The Commission's estimate of 7,600 m<sup>3</sup> for irrigating one cropped hectare does not appear to have taken water losses sufficiently into account.

<sup>10</sup> The principal capital investment in the Plan for all four regions would be for the expansion of the irrigated area: over all by 94 per cent, ranging from 39 per cent in the Near East and North-west Africa to 107 per cent in Asia and the Far East. Chemical fertilizers, which are effective in raising yields primarily in irrigated lands, could thus be used over a much larger area in 1985 than in 1962.

<sup>11</sup> Food and Agriculture Organization of the United Nations, *op. cit.*

<sup>12</sup> Government of India, Ministry of Irrigation and Power, *Report of the Irrigation Commission, 1972* (New Delhi, 1972), vol. I, chaps. III and X, pp. 41-58 and 201-246.

<sup>7</sup> *Ibid.*

<sup>8</sup> *Ibid.*

<sup>9</sup> Food and Agriculture Organization of the United Nations, *op. cit.*

Hence, their estimate of a total water use of 616 thousand million m<sup>3</sup> for irrigating some 80 million gross cropped hectares is probably low, and there may ultimately be a serious conflict for water between agricultural and industrial and municipal users.

37. Thailand's primate metropolis, Bangkok-Thon Buri, gives another example. The city's population is growing at between 5 and 6 per cent per annum, and the country as a whole at about 3 per cent, doubling in around 23 years. The metropolitan water-supply comes from two sources: wells under the city and a diversion point on the Chao Phraya river some 30 km to the north.<sup>13</sup>

38. With the rapid increase in food demand, caused by population growth and rising incomes in Thailand, more and more of the Chao Phraya waters are being used for irrigation agriculture above the city's diversion point. During the low-flow season, the volume of fresh water remaining in the river, even when supplemented by water pumped from wells under the city, is not much more than that required for municipal use by the current population of Bangkok. The water-table under the city is being lowered by the pumping, and there is danger of subsidence and of salt-water intrusion into the river and the underground aquifer.

39. The problem of water quantity for both the city and the farmers could probably be solved by constructing up-stream dams and reservoirs to augment the low flow and by digging tube-wells in the agricultural areas, which could be used instead of the river as a source of irrigation water during the dry season. The aquifers supplying these tube-wells would be recharged during the monsoon.

40. An intrinsic feature of the Aswan High Dam in Egypt is that the water can be used for another principal purpose besides irrigation agriculture—hydro-electric power. The annual amount of electric energy that can be produced by the generators and turbines of the dam was planned as about 10 thousand million kilowatt hours. This would approximately double the electrical energy now available to Egypt. To use this energy effectively for industrial development, it must be generated at the times and in the amounts needed. Because most industries need to operate at a fairly steady rate throughout the year, their electric-power requirements are about the same during each season.

41. In contrast, agricultural needs for water vary widely from one season to another. Because air temperatures are higher and there is more sunshine in the summer, crop plants transpire to the atmosphere between two and three times as much water in summer as in winter. If about the same area of land is cultivated through the year (such intensive cultivation not only is traditional in Egypt, but is essential for efficient agriculture), the amount of water required for irrigation will be much higher in the summer than in the winter.

42. If water is released from the dam in such a way as to provide optimum economic benefits for agriculture, the large variations from month to month in the rate of generation of electric power are far from optimum for industry. On the other hand, if the water is released in accordance with the needs for electrical power, there is too much water for agriculture in fall and winter, and not enough in the summer.

43. A preliminary analysis<sup>14</sup> shows, however, that the dam is well adapted to multiple use; that is, it could effectively satisfy a relatively high proportion of the needs, both for irrigation water and for power, if the river water could be used conjunctively with ground water in Lower Egypt, from Cairo through a large part of the delta, where there is an enormous reservoir of fresh underground water equal in volume to several years flow of the Nile. Such a combined use of surface and underground water would also allow the farmers greater flexibility in the timing of irrigation, facilitate the maintenance of the water-table at the proper level to minimize evaporation loss and salination and make it possible to irrigate lands above the level of canal commands.

#### *Conflicts in land use*

44. In regions of traditional nomad grazing, such as the north-west frontier of Pakistan and the sub-Saharan savannah belt of Africa, the establishment of modern high-intensity agriculture encounters severe difficulties, both from the cultural patterns of the people and from the conflicting needs of cattlemen and farmers for land. Forest industries and agriculture also conflict in ways that may have serious economic consequences. A large fraction of the currently uncultivated land is now covered by forests. The clearing of the forests for low-yielding, subsistence agriculture may represent a serious economic loss.

45. Many major irrigation projects involve the construction of large high dams and reservoirs behind them. These reservoirs commonly flood valuable river-bottom lands which have high actual and potential agricultural value. The problems of resettling the agricultural peoples displaced by the reservoirs have not been completely solved in any country.

46. The growth of cities commonly utilizes prime agricultural land. Fortunately, the total area of cities is small, usually less than 5 per cent of the land area of even a highly urbanized country.

#### *Effects of differential agricultural development*

47. The new agricultural technology is much better suited to some regions than to others. For example, in India, irrigation development is easy to accomplish in the Ganga plains of Uttar Pradesh and Bihar; it is difficult and expensive in most of the Deccan plateau, which covers central India. National farm prices will

<sup>13</sup> P. Cheosakul and B. Indranparan, personal communication to the author; 1971.

<sup>14</sup> H. A. Thomas, Jr., and R. Revelle, "On the efficient use of High Aswan Dam for hydropower and irrigation", *Management Science*, vol. XII, No. 8 (April 1966), pp. B296-B311.

almost certainly fall because of greatly expanded production in the regions in which the new technology can be successfully applied. The farmers in the less favoured regions may then be unable to sell their crops at prices sufficient to pay for the water, chemical fertilizers and other inputs needed for high-productivity agriculture. They will be forced back to subsistence farming, but this will be insufficient to feed the growing populations of their own villages. Large numbers of poverty-stricken and unskilled countrymen will be driven out, either to cities and towns or to the more favoured agricultural regions, where most of them will become landless labourers. The challenge to policy-makers, either to develop new agricultural technologies for non-irrigated land, or to provide employment and a new way of life for these people, is very great, especially because of the difficulties of raising employment in the industrial sector as fast as the labour force grows.<sup>15</sup>

#### *Potential irrigation development in India*

48. The Indian Irrigation Commission estimated that 84.2 million gross cropped hectares could ultimately be put under irrigation in India. The area under irrigation would be about 50 per cent of the net cropped area, leaving around 69 million hectares unirrigated. The Commission's estimated cost for future irrigation development was Rs. 3,000 per net irrigated hectare, or a total of approximately Rs. 100 million (\$14 thousand million); and they believed this development could take place in the next 30 years. The current gross cropped irrigated area would be increased by 158 per cent, or 51.6 million hectares.

49. The data given by the Commission indicate that yields of human food per crop on irrigated land in India are equivalent to 2 tons of food-grains per hectare ( $7 \times 10^6$  kcal). This is more than twice the yield on unirrigated land. Current yields of cotton are 350 kg per hectare on irrigated land, and about 100 kg on unirrigated land. With the current cotton yields and a cotton demand of 2.5 kg per person per year, the Indian population of 900 million, assumed by the Commission in the year 2000, would require 2,250,000 tons of cotton, and 6,400,000 hectares of irrigated land would need to be allocated to cotton production.

50. Assuming current food yields, the remaining 147 million gross cropped hectares could produce the equivalent of 225 million tons of food-grains. Subtracting 13 per cent for seed, feed and wastage, 196 million tons could be available for human consumption, giving an average daily diet of 2,100 kcal per person per day, about the same as the current diet, for 900 million people. Unfortunately, with the current rate of population growth in India (2.2 per cent per annum), this population would be attained in 1992-1993, seven years before the terminal date of irrigation development set by the Commission. Continuance of a minimum

diet for the majority of the population would minimize the prospects for socio-economic development, and hence, for a reduction in fertility rates. The future for the next generation would be bleak.

51. On the other hand, if socio-economic development can occur, based on increased agricultural productivity, powerful forces for fertility reduction could be set in motion and population growth could gradually be brought to a halt. If, for example, a population of 1.2 thousand million is assumed during the first half of the twenty-first century, together with yields equivalent to 6 tons of food grains and 500 kg of cotton per gross cropped hectare of irrigated land, and 1 ton of food-grains per hectare on unirrigated land, then the average diet could be greatly improved. Yields of this magnitude have already been attained in Egypt and in some other less developed countries.<sup>16</sup>

52. The total plant energy available for the average Indian diet would be the equivalent of about 3,700 kcal per person per day (assuming an increase in cotton demand to 3 kg per person per year). This would allow *per capita* consumption of around 25 grams of animal protein from milk, eggs and poultry, nearly half the average daily protein requirement<sup>17</sup> and an average dietary energy content of 2,400 kcal.<sup>18</sup> This amount is 200-300 calories more than the current rate—the increase would be required because of the declining proportion of children, as birth rates decline.

53. Such a transformation of Indian agriculture would not be constrained by a lack of water and land resources, but by the levels of knowledge and incentives that could be made available to the farmers, the quantities of capital and the institutional changes that could be devoted to agricultural development and, possibly, by the future availability of energy resources. Even if the total capital requirements were three times those estimated by the Irrigation Commission, the

<sup>16</sup> D. Pimentel and others, *op. cit.*

<sup>17</sup> G. A. Goldsmith and others, "Population and nutritional demands", in United States of America, President's Science Advisory Committee, *The World Food Problem*, report of the Panel on the World Food Supply (Washington, D.C., Government Printing Office, 1967), vol. II, chap. 1, pp. 5-135.

<sup>18</sup> The method of calculation may be illustrated by supposing that all animal protein comes from cow's milk. One kilogramme of milk contains 35 grams of protein and has an energy content of 650 kcal; see B. K. Watt and A. L. Merrill, *Composition of Foods*, Agricultural Handbook No. 8 (Washington, D.C., United States Department of Agriculture, 1963), p. 63. Then, 25 grams of protein and 465 kcal are contained in 715 grams of milk. Dairy cows are about 23 per cent efficient in converting plant protein and energy into milk protein and energy; see G. A. Goldsmith and others, "Increasing high quality protein", in United States of America, President's Science Advisory Committee, *The World Food Problem*, report of the Panel on the World Food Supply (Washington, D.C., Government Printing Office, 1967), vol. II, chap. V, pp. 299-371. Hence, 465 kcal of milk correspond to 2,000 kcal of plant energy, and 2,000 kcal plus 2,400, minus 465, equals 3,935 kcal per person per day of primary plant food energy. Since part of the animal feed would be the humanly inedible portion of the crop, it may be estimated that about 3,700 kcal of humanly edible food per person per day is the basic plant energy available in an India of 1.2 thousand million people, with a modernized agriculture using 1970 technology.

<sup>15</sup> National Academy of Sciences, *Rapid Population Growth: Consequences and Policy Implications* (Baltimore, Maryland, Johns Hopkins Press, 1971), vol. I, chap. 4.

needed annual investment would be only about 2 per cent of the current gross national product of India.

#### *Agricultural development in Bangladesh*

54. A more serious situation can be projected for Bangladesh. Careful studies by the International Bank for Reconstruction and Development and the Harvard Center for Population Studies<sup>19</sup> have shown that with a total new capital investment of Rs. 7.9 thousand million (\$1,780 million), yield of food-grains on 8,940,000 net cultivated hectares could be more than doubled during the next 20 years, to 2.5 tons per net hectare. Allowing for seed, feed and wastage, the annual rice and wheat production available for human consumption would be about 20 million tons, barely enough, since food-grains constitute about 82 per cent of the energy content of the diet, for a minimum diet for the 134 million people anticipated in 1993 (with a rate of natural increase at that time of 2.5 per cent per annum). Modernization of agriculture, near to the levels that were described earlier in this paper, might allow another doubling of food-grain production, perhaps to 40 million tons; but self-sufficiency in food production could not be long sustained in the face of continuing population growth. The problem is urgent and potentially tragic. Both agricultural development and industrial development for exports to pay for food will be necessary, possibly combined with out-migration on a large scale.

#### *Sub-Saharan Africa*

55. After several years of drought, severe food deficiencies have become widespread in the belt of semi-arid steppe and brush-grass savannah that extends across Africa south of the Sahara Desert. This belt is becoming narrowed on its northern side by desertification—the steady march of wind-blown sands—and its use for cattle-grazing is limited on the south by the tse-tse fly. Pastoral nomads comprise a large segment of the human population of some 25 million; most of the remainder live on a meagre subsistence agriculture. Parts of the area are traversed by large rivers, which are said to carry annually about 180 thousand million m<sup>3</sup>. Three large ground-water reservoirs are believed to contain close to 6,000 thousand million m<sup>3</sup>. The rate of recharge of the ground-water reservoirs is said to be only about 1.5 thousand million m<sup>3</sup> per annum.<sup>20</sup> This undoubtedly could be greatly increased by draining down the water-table sufficiently to allow percolation into the reservoirs and to reduce evaporation losses from them. The quality of the ground water and its suitability

for irrigation are not well known. Alternative long-term courses of land and water development, which might prevent a recurrence of current disastrous conditions, are: range improvement; better range management; development of subsistence agricultural areas and resettlement of the population in these areas; and development of areas of intensive irrigation agriculture and resettlement of the population in those areas.

56. In examining these alternatives, many technical factors must be considered, but social, political and economic constraints are undoubtedly more fundamental. Rapid development would be essential if the conditions of life and the aspirations of the people are to be raised. Otherwise, population growth would almost certainly keep up with increasing food supplies and the final outcome would be a more desperate situation than that which now exists. The countries of the region have very limited capital and technical resources. In the early stages, these would have to be supplemented by the world community, particularly the rich countries and the commitment of these countries to the needed level of capital and technical assistance for the poor countries has been diminishing for a decade.

#### CONCLUSIONS

57. The quantity of potentially arable land on earth is so much larger than the area actually cultivated today, and the possibilities for increasing agricultural production on currently cultivated lands are so great, that the area of the earth's surface that will be devoted to agriculture in the future is chiefly an economic and social variable, which differs from country to country, rather than a physical one.<sup>21</sup>

58. Agricultural modernization in the less developed countries is essential if the growing populations of the world are to be fed. Such modernization depends upon over-all social and economic development, as well as upon the development, application and dispersal of knowledge.<sup>22</sup>

59. Social and economic development (increases in *per capita* incomes and a more equitable income distribution) is probably also a necessary condition for a significant and continuing reduction in rates of population growth and ultimately for a stationary world population.

60. Man is faced with a paradox: attainment of the earth's maximum carrying capacity for human beings would require a very large degree of agricultural modernization, and hence, social and economic development. But such development would be likely to lead to a cessation of population growth long before the maximum carrying capacity was reached.

61. The less developed countries confront a more immediate circularity. In terms of both employment

<sup>22</sup> *Ibid.*

and production, agriculture is an overwhelmingly important component of their economies. Agricultural modernization is essential for their over-all economic development because it will create a consumer surplus which can be saved and invested in other economic sectors. At the same time, however, agricultural modernization depends upon over-all economic development because it requires many inputs from outside agriculture and a large and growing market for agricultural products.

62. Ecological deterioration caused by human agricultural activities is much more likely to occur through the expansion of traditional agriculture into an unsuitable or easily damaged environment than through agricultural modernization, which, from many points of view, leads to environmental improvement.<sup>23</sup> Nevertheless, agricultural modernization, particularly

---

<sup>23</sup> *Ibid.*

the use of wide-spectrum pesticides and excessive quantities of fertilizer and the elimination of potentially valuable components of plant and animal gene pools, has also been environmentally destructive. One of the kinds of knowledge that needs to be sought through research is that necessary to minimize environmental deterioration.

63. Agricultural modernization in the less developed countries is one of the great challenges facing mankind. For future human welfare, it must take place much more rapidly than population growth, so that levels of living can be raised and opportunities for improvements in the conditions of life can be increased. If it does not take place quickly, it may not be possible at all. The developed countries have an essential role to play in the first stages of this modernization because they possess a large share of mankind's ability to gain the needed knowledge through research.

## WORLD POPULATION AND FOOD SUPPLIES: LOOKING AHEAD

Lester R. Brown\*

1. The international scarcity of major agricultural commodities in 1973 reflected important long-term trends as well as the more temporary phenomenon of lack of rainfall in the Union of Soviet Socialist Republics and in parts of Asia and Africa. It appears that an extended period is beginning in which global grain reserves, which provide a crucial measure of safety when crop failures occur, will generally remain on the low side, and in which little, if any, excess cropland will be held idle in the United States of America. Food prices are likely to remain considerably higher than they were during the past decade, placing a special burden on the world's poor. Meanwhile, the world has become overwhelmingly dependent upon one continent—North America—for exportable food supplies. From a global perspective, the world is likely to be in a vulnerable situation on the food front in the years ahead. Strong international policy responses are called for in an area so basic to human welfare.

### POPULATION AND AFFLUENCE

2. During the 1960s, the world food problem was perceived as a food/population problem centred on the developing countries, a race between food and people. At the end of each year, observers anxiously compared rates of increase in food production with those of population growth to see if any progress was being made. Throughout most of the decade it was nip and tuck. During the 1970s, rapid global population growth has continued to generate demand for more food; but, in addition, rising affluence is emerging as a major new claimant on the world's food resources. Thus, there are now two important sources of growth in world demand for food.

3. On a world-wide basis, population growth is still the dominant source of expanding demand for food. With world population expanding at nearly 2 per cent per annum, merely maintaining current *per capita* consumption levels will require a doubling of food production in little more than a generation.

4. Throughout the poor countries, population growth accounts for most of the year-to-year growth in the demand for food. At best, only very limited progress is being made in raising *per capita* consumption. In the

more affluent countries, on the other hand, rising incomes account for most of the growth in the demand for food.

5. The effect of rising affluence on the world demand for food is perhaps best understood by examining its effect on requirements for cereals, which dominate the world food economy. In the poor countries, the annual availability of grain per person averages only about 400 pounds per year. Nearly all of this small amount, roughly a pound a day, must be consumed directly to meet minimum energy needs. Little can be spared for conversion into animal protein.

6. In the United States and Canada, *per capita* grain utilization is currently approaching 1 ton per annum. Of this total, only about 150 pounds are consumed directly in the form of bread, pastries and breakfast cereals. The remainder is consumed indirectly in the form of meat, milk and eggs. The agricultural resources—land, water, fertilizer—required to support an average North American are nearly five times those of the average Indian, Nigerian or Colombian.

7. In the northern tier of industrial countries stretching from the United Kingdom of Great Britain and Northern Ireland, and Europe through the Soviet Union to Japan, dietary habits more or less approximate those of the United States in 1940. As incomes continue to rise in this group of countries (which contain some 660 million people), a sizable share of the additional income is being converted into demand for livestock products, particularly beef. Many of these countries lack the capacity to satisfy the growth in their demand for livestock products entirely from indigenous resources. As a result, they are importing increasing amounts of livestock products or of feed-grains and soya beans with which to expand their livestock production.

### SCARCE RESOURCES: LAND, WATER AND ENERGY

8. As the world demand for food climbs, constraints on efforts to further expand food production become increasingly apparent. The means of expanding food supplies from conventional agriculture fall into two categories: either increasing the amount of land under cultivation; or raising yields on existing cropland through intensified use of water, energy and fertilizers. Problems exist in the needed expansion of each of these resources.

\* Senior Fellow, Overseas Development Council, Washington, D.C.

9. From the beginning of agriculture until about 1950, expanding the cultivated area was the major means of increasing the world's food supply. Since 1950, however, raising output on the existing cultivated area has accounted for most of the increase. Intensification of cultivation has increased steadily since 1950; during the early 1970s, it has accounted for an estimated four fifths of the annual growth in world food output, far overshadowing expansion of the cultivated area.

10. The traditional approach to increasing production—expanding the area under cultivation—has only limited scope for the future. Indeed, some parts of the world face a net reduction in agricultural land because of the growth in competing uses, such as recreation, transportation and industrial and residential development. Few countries have well-defined land-use policies that protect agricultural land from other uses. In the United States, farmland has been used indiscriminately for other purposes with little thought devoted to the possible long-term consequences.

11. Some more densely populated countries, such as Japan and several Western European countries, have been experiencing a reduction in the land used for crop production for the past few decades. Other parts of the world, including particularly the Indian subcontinent, the Middle East, North Africa, the Caribbean, Central America and the Andean countries, are losing disturbingly large acreages of cropland each year because of severe soil erosion.

12. The availability of arable land is important, but perhaps even more important in the future will be the availability of water for agricultural purposes. In many regions of the world, fertile agricultural land is available if water can be found to make it produce. Yet most of the rivers that lend themselves to damming and to irrigation have already been developed. The expansion of world irrigated area is likely to fall into the familiar S-shaped curve as man runs out of easy opportunities to construct new irrigation reservoirs. Future efforts to expand fresh-water supplies for agricultural purposes will increasingly focus on such techniques as the diversion of rivers (as in the Soviet Union), the manipulation of rainfall patterns to increase the share of rain falling over moisture-deficient agricultural areas and, depending upon the cost of energy, the desalting of sea water.

13. The intensification of agricultural production on the existing cultivated area in many developing countries requires a several-fold increase in energy supplies. With world energy prices rising rapidly, the costs of intensifying food production will rise commensurately and the needed increases in energy use will become increasingly expensive. In countries already engaged in high energy agriculture, such as the United States, Japan and those in Western Europe, high energy prices and the possibility of fuel rationing may reduce future food production prospects below what they would otherwise be.

14. In addition to arable land, fresh water and

energy, fertilizer is also now in short supply, and the outlook is for higher prices. It is impossible to separate the future availability of fertilizer from the scarcity of energy. In part this is because the manufacture of nitrogen fertilizer, the most widely used chemical fertilizer, commonly utilizes natural gas or naphtha as a raw material and in part because the manufacturing process consumes large amounts of energy. Fertilizer requirements over the remaining years of this century will soar to phenomenal levels.

15. One of the key questions concerning future gains in agricultural production is whether the more advanced countries can sustain the trend of rising per acre yields of cereals. In some countries, the rate of increase in per acre yields for some crops is beginning to slow down and the capital investments required for each additional increase may now begin to climb sharply. In agriculturally advanced countries, such as Japan and some countries in Europe, the cost of further raising yield per acre for some crops is rising. For example, raising rice yields in Japan from the current 5,000 pounds per acre to 6,000 pounds could be very costly. Raising yields of corn in the United States from 90 to 100 bushels per acre requires a much larger quantity of nitrogen than was needed to raise yields from 50 to 60 bushels. Higher fertilizer prices will, in this context, further reduce the potential for continuing yield increases.

#### CONSTRAINTS ON PROTEIN PRODUCTION

16. At a time when rising affluence is beginning to manifest itself in the form of rapidly growing demand for high-quality protein, a difficulty has suddenly arisen in the efforts to rapidly expand supplies of three major protein sources—beef, soya beans and fish. Two major constraints are operative in the case of beef. Agricultural scientists have not been able to devise any commercially satisfactory means of getting more than one calf per cow per year. For every animal that goes into the beef production process, one adult animal must be fed and otherwise maintained for a full year. There does not appear to be any prospect of an imminent breakthrough on this front.

17. The other constraint on beef production is good grassland. The grazing capacity of much of the world's pasture land is now almost fully utilized. This is true, for example, in much of the Great Plains area of the United States, in sub-Saharan Africa and in parts of Australia. There are opportunities for using improved grasses and for improved range management, but these are limited and slow to be realized.

18. A second potentially serious constraint on efforts to expand supplies of high-quality protein is the inability of scientists to achieve a breakthrough in per acre yields of soya beans. Soya beans are consumed directly as food by people throughout densely populated East Asia, and they are an important high-quality protein ingredient in livestock and poultry feeds throughout much of the world. The economic importance of soya

beans in the world food economy is indicated by the fact that they have become the leading export product of the United States of America, surpassing export sales of wheat, corn and such high-technology items as electronic computers and jet aircraft.

19. In the United States, which now produces two thirds of the world's soya bean crop and supplies more than four fifths of all soya beans entering the world market, the yields per acre have increased by about 1 per cent per annum since 1950; corn yields, on the other hand, have increased by nearly 4 per cent per annum. One reason why soya bean yields have not climbed very rapidly is that the soya bean, being a legume with a built-in nitrogen supply, is not very responsive to nitrogen fertilizer.

20. More soya beans are produced essentially by planting more land to soya beans. In the United States, close to 85 per cent of the dramatic fourfold increase in the soya bean crop since 1950 has come from expanding the area devoted to it. As long as there was ample idle cropland available, this did not pose a problem, but with this cropland reserve rapidly disappearing and with one in every six acres of cropland in the United States already planted to soya beans by 1973, serious supply problems could emerge.

21. The oceans are a third major source of protein. From 1950 to 1970, the world fish catch expanded rapidly, going from 21 million to 70 million tons. This phenomenal growth in the catch of nearly 5 per cent annually, which far exceeded the annual rate of world population growth, greatly increased the average supply of marine protein per person. This is shown in table 1.

TABLE 1. WORLD FISH CATCH: TOTAL AND *per capita*

Year	Total catch (million metric tons)	Per capita (kilogrammes)
1950	21	8
1951	24	10
1952	25	10
1953	25	10
1954	28	10
1955	29	11
1956	30	11
1957	32	11
1958	33	12
1959	36	13
1960	40	14
1961	43	14
1962	46	15
1963	48	15
1964	52	16
1965	52	16
1966	57	17
1967	60	18
1968	63	18
1969	63	18
1970	70	19
1971	69	19
1972 <sup>a</sup>	64	17
1973 <sup>a</sup>	62	16

<sup>a</sup> Preliminary figure.

22. In 1969, the long period of sustained growth in the world fish catch was interrupted by a slight decline of a few hundred thousand tons. In 1970, the catch resumed its upward trend, but the sharp rebound was short-lived. Since then, it has declined for three consecutive years, falling some 8 million tons. With population continuing to grow, the *per capita* availability of fish declined 16 per cent during this three-year span, triggering dramatic price rises. As stocks of some key commercial species are depleted, the amount of time and money expended to bring in the shrinking catch continue to rise every year. Many marine biologists now feel that the global catch of table-grade fish is at or near the maximum sustainable level. A large number of the 30 or so leading species of commercial-grade fish currently may be over-fished, that is, stocks will not sustain even the current level of catch. If the world fish catch stabilizes or declines, then that share of the growing global demand for protein until recently filled by growth in the fish catch, must now either be filled by land-based protein supplies or it must be choked off by further price rises. The importance of evolving a co-operative international approach to the management of oceanic fisheries is underlined.

23. Unfortunately, there is no prospect whatsoever that fish-farming could offset more than a small fraction of the decline in the oceanic fish catch for the foreseeable future. Substantial expansion in the global fish supply from fish-farming await further advances in technology and extensive capital investment in fish-farming facilities.

24. Although there are substantial opportunities for expanding the world food supply, it now seems likely that the supply of food, particularly protein, will lag behind growth in demand for some time to come, resulting in significantly higher prices during the decade ahead than prevailed during the 1960s. It may be that the world protein market will be transformed from a buyer's market to a seller's market, much as the world energy market has been transformed over the past few years.

#### ECOLOGICAL UNDERMINING OF THE WORLD FOOD ECONOMY

25. The increasing demand for food is putting more pressure on the food-producing ecosystem in many parts of the world than it can withstand. One dramatic example is the anchovy fishery off the western coast of Latin America. During the early 1970s, this vast fishery accounted for one fifth of the global fish catch. During late 1972 and throughout much of 1973, the anchovies seemingly disappeared from the traditional off-shore fishing areas. This did not cause a great deal of alarm since a slight shift in the Humboldt current and the change in temperature of a few degrees had caused the anchovies to move away at least temporarily before.

26. There is now growing evidence that the very heavy off-take from the anchovy fishery ranging from

10 million to 12 million tons in the late 1960s and early 1970s may have exceeded the capacity of the fishery to regenerate itself. Over-fishing may have seriously damaged the anchovy fishery. If so, it may take years before it can recover to its full productive capacity, assuming it is given the opportunity to do so.

27. A second example of ecological over-stress, which is diminishing the earth's food-producing capacity, is now all too evident in the Sahel, just south of the Sahara in Africa. For many months in 1973, the news media reported the situation in sub-Saharan Africa as being the product of drought. The problem was described in terms of the need for a temporary food relief effort. The need was to get perhaps 600,000 tons of grain into half a dozen seriously affected countries over the next several months. This was indeed a problem. The need was real.

28. However, there is a much more basic problem in the Sahel. Over the past 35 years, human and livestock populations along the sub-Saharan fringe have increased rapidly, in some areas nearly doubling during this period. As the human and livestock populations multiply, they put more pressure on the ecosystem than it can withstand. The result is over-grazing, deforestation and over-all denudation of the land.

29. As a result of this denudation and deforestation, the Sahara desert has begun to move southward at an accelerated rate all along the 3,500 mile southern fringe, stretching from Senegal to northern Ethiopia. An "in-house" study undertaken by the United States Agency for International Development in August 1972 indicated the desert is moving southward at up to 30 miles per year, depending upon where it is measured.

30. As the desert moves southward, human and livestock populations retreat before it. The result is ever-greater pressure on the fringe area. This in turn contributes to the denudation and deforestation, setting in process a self-reinforcing cycle.

31. Coping with this situation requires far more than a temporary food relief effort. The world must recognize that a continuing food relief effort for this region will be required for the foreseeable future. But this treats only the symptoms of ecological over-stress. There is also now a need to attempt to arrest and reverse the southward movement of the desert. This will require an extensive infusion of technical expertise in desert reclamation and land management from outside the region. It will require economic resources from outside the region until some of the desert land can be reclaimed.

32. There is now a pressing need to address and alleviate the causes of ecological stress in the region which facilitates the southward movement of the Sahara. Failure to do so means the Sahara may engulf much of central Africa in a matter of years, destroying a significant slice of the continent's food-producing capacity. It will require, among other things, a concerted co-operative effort by the tier of countries most imme-

diately affected, by the next tier of countries southward which is or will shortly be affected, and by a large number of external donors who must supply much of the resources. Above all, it calls for the launching of efforts to slow and stabilize population growth in the region.

33. The need to arrest the southward movement of the desert presents the international community with one of its most severe challenges. It will require a co-operative international effort comparable with that which was used to launch the "green revolution" in the late 1960s. If this co-operative effort is not forthcoming, one must accept the fact that a growing share of the food-producing capability of Africa will be totally destroyed. This is occurring at a time when population in the African continent is still expanding in an unimpeded fashion.

34. Ecological over-stress is also very much in evidence in the Indian subcontinent. Over the past 15 years, as human and livestock populations have increased, the subcontinent has been progressively deforested. One does not need much training in soil and water management to be greatly alarmed at the long-term consequences of this progressive and accelerating deforestation. This is most serious in the Himalayas and the surrounding foot-hills, for this is where nearly all the major river systems of the Indian subcontinent—the Indus, the Ganges and the Bramaputra—originate.

35. One could have predicted several years ago with great confidence the long-term dangers inherent in deforestation, particularly of the Himalayas and the surrounding foot-hills. It should not have come as any surprise that during the late summer of 1973 reports came of the worst flood in the history of Pakistan, a flood so severe that it destroyed a large share of the spring wheat crop which was in storage on farms as well as a sizable share of the crops standing in the fields. Entire communities were washed away.

36. Since the deforestation is continuing, one can now say with considerable confidence that the incidence and severity of flooding in Pakistan, India and Bangladesh will be much greater in the future than it is at present. In effect, deforestation in the subcontinent, particularly in Nepal where the major rivers originate, may be undermining the food-producing capability of the subcontinent upon which nearly 750 million people now depend.

37. The pressures of continuously growing demand for food are beginning to undermine the food-producing ecosystems in many parts of the world. The examples given above are only a few of the many which could be cited. The time has come to inventory systematically these ecological stresses at the global level. Two generalizations can be made concerning agricultural stresses on the ecosystem. First, the situation is certain to worsen in the years immediately ahead; and, secondly, future world food production prospects will be affected.

THE "GREEN REVOLUTION": OPPORTUNITY LOST?

38. Efforts to modernize agriculture in the less affluent countries in the 1950s and early 1960s were consistently frustrated. When farmers in these countries attempted to use varieties of corn developed in Iowa, they often failed to produce any corn at all. Japanese rice varieties were not suited either to local cultural practices or to consumer tastes in India. When fertilizer was applied intensively to local cereal varieties, the yield response was limited and occasionally even negative.

39. It was against this backdrop of frustration that the high-yielding dwarf wheats were developed by the Rockefeller Foundation team in Mexico. Three unique characteristics of these wheats endeared them to farmers in many countries—their fertilizer responsiveness, lack of photo-period sensitivity (sensitivity to day length) and early maturity.

40. When farmers applied more than 40 pounds of nitrogen fertilizer per acre to traditional varieties having tall, thin straw, the wheat often lodged or fell over, causing severe crop losses. By contrast, yields of the short, stiff-strawed dwarf varieties of Mexican wheat would continue to rise with nitrogen applications of up to 120 pounds per acre. Given the necessary fertilizer and water and the appropriate management, farmers could easily double the yields of indigenous varieties.

41. Beyond this, the reduced sensitivity of dwarf varieties to day length permitted them to be moved around the world over a wide range of latitudes, stretching from Mexico, which lies partially in the tropics, to Turkey in the temperate zone. Because the biological clocks of the new wheats were much less sensitive than those of the traditional ones, planting dates were much more flexible.

42. Another advantageous characteristic of the new wheats was their early maturity. They were ready for harvest within 120 days after planting; the traditional varieties took 150 days or more. This trait, combined with reduced sensitivity to day length, created broad new opportunities for multiple cropping wherever water supplies were sufficient.

43. Within a few years after the spectacular breakthrough with wheat in Mexico, the Ford Foundation joined the Rockefeller Foundation to establish the International Rice Research Institute (IRRI) in the Philippines. Its purpose was to attempt to breed a fertilizer-responsive, early maturing rice capable of wide adaptation—in effect, a counterpart of the high-yielding wheats. With the wheat experience to draw upon, agricultural scientists at IRRI struck "pay dirt" quickly. Within a few years they released the first of the high-yielding dwarf rices, a variety known as IR-8.

44. The great advantage of the new seeds was that they permitted developing countries to quickly utilize agricultural research that had taken decades to complete in Japan, the United States and elsewhere. In those areas of the developing countries where there were requisite supplies of water and fertilizer and price

incentives were offered, the spread of the high-yielding varieties of wheat and rice was rapid. Farmers assumed to be bound by tradition were quick to adopt the new seeds when it was obviously profitable for them to do so.

45. Early in 1968, the term "green revolution" was coined to describe the introduction and rapid spread of the high-yielding wheats and rices. In 1965, land planted with these new varieties in Asia totalled about 200 acres, largely trial and demonstration plots. Thereafter the acreage spread swiftly as follows:

Year	Acres
1965	200
1966	41,000
1967	4,047,000
1968	16,660,000
1969	31,319,000
1970	43,914,000
1971	50,549,000

46. Acreage figures for Mexico are not included in the series given above since the new wheat had largely displaced traditional varieties before the green revolution became an international phenomenon in the mid-1960s. Among the principal Asian countries to benefit from using the new seeds are India, Pakistan, the Philippines and Turkey, and, more recently, Indonesia, Malaysia and Sri Lanka.

47. During the late 1960s, the Philippines was able to achieve self-sufficiency in rice, ending half a century of dependence on imported rice. Unfortunately, this situation was not sustained because of a number of factors, including civil unrest, the susceptibility of the new rices to disease and governmental failure in some cases to continue the essential support of the rice programme.

48. Pakistan has greatly increased its wheat production, emerging as a net exporter of grain in recent years. In India, where advances in the new varieties were concentrated largely in wheat, progress has been encouraging. During the seven-year span from 1965 to 1972, India expanded its wheat production from 11 million tons to 27 million tons, an increase in a major crop unmatched by any other country in history.

49. One result of this dramatic advance in wheat production in India was the accumulation of unprecedented cereal reserves and the attainment of cereal self-sufficiency in 1972. This eliminated, at least temporarily, the need for imports into a country that only a few years before had been the principal recipient of food aid from the United States of America. Economic self-sufficiency in cereals—when farmers produce as much as consumers can afford at prevailing prices—is not to be confused with nutritional self-sufficiency, however, which requires much higher levels of productivity and purchasing power.

50. During late 1971 and in 1972, India was able to use nearly 2 million tons from its own food reserves, at first to feed nearly 10 million Bengali refugees during the civil war in Pakistan, and later as food aid for

Bangladesh. A poor monsoon in 1972 temporarily forced India back into the world market as an importer of grain, but on a much smaller scale—4 million tons—than the massive import of nearly 10 million tons that followed the 1965 monsoon failure.

51. This is not to suggest that the green revolution has solved the world's food problems, on either a short- or a long-term basis. The drought of 1973 clearly demonstrated that Indian agriculture is still at the mercy of the vagaries of weather. A second monsoon failure or a shortage of fertilizer would seriously disrupt the pattern of progress that has characterized Indian agriculture over the past five years.

52. The green revolution can be properly assessed only when it is considered what things would have been like in its absence. The grim scenario that this question calls forth lends some of the needed perspective. Increases in cereal production made possible by the new seeds did arrest the deteriorating trend in *per capita* food production in the developing countries. The massive famine anticipated by many has been avoided. Although there have been some spectacular localized successes in raising cereal output, relatively little progress has been made in raising the *per capita* production of cereals among the less affluent countries as a whole over the past several years.

53. The green revolution does not represent a solution to the food problem; rather, it is a means of buying time, perhaps an additional 15 or 20 years during which the brakes can be applied to population growth. Close to a decade has now passed since the launching of the green revolution, but success stories in national family planning programmes in the less affluent countries are all too few. For example, reductions in birth rates are minimal in Bangladesh, India, Indonesia and Pakistan.

#### DEPLETED GLOBAL RESERVES

54. The period since the Second World War has been characterized by excess capacity in world agriculture, much of it concentrated in the United States of America. In many ways the world was fortunate to have, in effect, two major food reserves during this period. One was in the form of grain reserves in the principal exporting countries and the other in the form of reserve cropland, virtually all of which was land idled under farm programmes in the United States.

55. Grain reserves, including substantial quantities of both food-grains and feed-grains, are most commonly measured in terms of carry-over stocks—the amount in storage at the time the new crop begins to come in. World carry-over stocks are concentrated in a few of the principal exporting countries—namely, Argentina, Australia, Canada and the United States.

56. Since 1960, world grain reserves have fluctuated from a high of 155 million metric tons to a low of about 100 million metric tons. When these reserves drop to 100 million tons, severe shortages and strong

upward price pressures develop. Although 100 million tons appears to be an enormous quantity of grain, it represents a mere 8 per cent of annual world grain consumption, or less than one month's needs—an uncomfortably small working reserve and a perilously thin buffer against the vagaries of weather or plant diseases. As world consumption expands by some 2.5 per cent per annum, so should the size of working reserves; but over the past two decades reserves have dwindled while consumption has continued to climb.

57. The second major source of stability in the world food economy throughout much of the post-war period has been the reserve of idle cropland in the United States: roughly 50 million acres have been idle under farm programmes for the past dozen years or so. Though not as quickly available as the grain reserves, most of this acreage can be brought back into production within from 12 to 18 months once the decision is made to do so.

58. In recent years, the need to draw down grain reserves and to utilize the reserve of idle cropland has occurred with increasing frequency. This first happened during the food crisis years of 1966 and 1967, when world grain reserves were reduced to a dangerously low level and the United States brought back into production a small portion of the 50 million idle acres. It happened again in 1971, as a result of the corn blight in the United States. In 1973, in response to growing food scarcities, world grain reserves once more declined and the United States again resorted to cultivating its idle cropland, but to a much greater degree than on either of the two previous occasions. Government decisions in early 1973 permitted much of the idle cropland to be brought back into production. In 1974, there will be no Government payments to keep cropland idle.

59. Reserve stocks fell to close to 100 million tons in 1973 and are not expected to be rebuilt in 1974. World grain reserves have now fallen to their lowest level in two decades, though the world population has increased by half in the interim.

60. By combining global reserve stocks with the potential grain production of idle cropland, a good indication may be obtained of the actual total reserve capability in the world food economy in any given year. Taking this total as a percentage of total world grain consumption then provides a rough quantitative indicator of global food security for the year. As table 2 demonstrates, the world is now in a situation of extreme vulnerability. In 1973 and 1974, world reserve capabilities in relation to consumption needs have fallen far below any previous level in the post-war era.

61. From the end of the Second World War until quite recently, world prices for the principal temperate zone farm commodities, such as wheat, feed-grains and soya beans, have been remarkably stable. In part, this is because throughout much of this period world prices have rested on the commodity support level in the United States. Since world food reserves may become chronically low and the idle crop acreage in the United

TABLE 2. INDEX OF WORLD FOOD SECURITY

Year	Reserve stocks of grain	Grain equivalent of idle cropland in United States (million metric tons)	Total reserves	Reserves as share of annual grain consumption (percentage)	Reserves as days of consumption
1961	154	68	222	26	94
1962	131	81	212	24	88
1963	125	70	195	21	77
1964	128	70	198	21	77
1965	113	71	184	19	69
1966	99	79	178	18	66
1967	100	51	151	15	55
1968	116	61	177	17	62
1969	136	73	209	19	69
1970	146	71	217	19	69
1971	120	41	161	14	51
1972	131	78	209	18	66

1974 <sup>a</sup>	89	0	89	7	27

<sup>a</sup> Projection.

States may decline sharply or even disappear entirely in the years ahead, there is the prospect of very volatile world prices for the important food commodities.

#### THE NORTH AMERICAN "BREADBASKET"

62. The extent of global vulnerability is particularly underlined by examining the degree of global dependence on North America for exportable food supplies. Over the past generation, the United States has achieved a unique position as a supplier of food to the rest of the world. Before the Second World War, both Latin America, especially Argentina, and North America (Canada and the United States) were major exporters of grain. During the late 1930s, net grain exports from Latin America were substantially above those of North America. Since then, however, the combination of the population explosion and the slowness of most Governments in Latin America to reform and modernize agriculture have eliminated the net export surplus. With few exceptions, Latin American countries are now food importers.

63. As table 3 illustrates, over the past three decades North America, particularly the United States, which accounts for three fourths of the continent's grain exports, has emerged as the world's "breadbasket". Exports of Australia, the only other net exporter of importance, are only a fraction of those of North America. The United States not only is the world's major exporter of wheat and feed-grains, it is now the world's leading exporter of rice. North America today controls a larger share of the world's exportable surplus of grains than the Middle East does of oil.

64. Exportable supplies of the crucial soya bean are even more concentrated than those of grains. The principal supplier is now the United States of America, which provided over 90 per cent of world soya bean exports in the 1960s and early 1970s. With world demand for high-quality protein surging upward, Brazil—virtually the only other country capable of producing soya beans on a sizable scale in the foreseeable future—has rapidly boosted its soya bean production and exports. However, the United States is

TABLE 3. CHANGING PATTERN OF WORLD GRAIN TRADE

(Million metric tons)

Note: Plus sign (+) indicates net exports; minus sign (-) indicates net imports.

<sup>a</sup> Preliminary figure.

likely to continue supplying three fourths or more of the world's soya bean exports for many years to come.

65. At a time when dependence of the rest of the world upon North American food exports is increasing so dramatically, there is also a growing awareness that this extreme dependence leaves the world in a very dangerous position in the event of adverse crop years in North America. Both Canada and the United States are affected by the same climatic cycles.

66. Considerable evidence has now been accumulated indicating that North America has been subject to recurrent clusters of drought years roughly every 20 years. The cyclical drought phenomenon has now been established as far back as the 1860s when data were first collected on rainfall. The most recent drought, occurring in the early 1950s, was rather modest. The preceding one occurring in the early 1930s was particularly severe, giving rise to the dust bowl era in the United States.

67. If the United States experiences another stretch of drought years, quite possibly during the current decade, its impact on production will not likely be as great as during the 1930s due to improved soil management and water conservation practices. But even a modest decline in production, given the rapid growth in global demand and extreme world dependence on the North American exportable margin of food, would create a very dangerous situation. It would send shock waves throughout the world, triggering intense competition for available food supplies.

#### REDEFINING FAMINE

68. High food prices and shortages are an inconvenience for the more affluent societies and individuals, but the less affluent countries, and the poor within countries, are in an especially dangerous predicament. When global reserve stocks are low, the capacity of the international community to respond to such emergencies as droughts or crop failures with food aid is greatly diminished. At the same time, high prices may keep needed food out of the reach of poor countries and individuals.

69. When one spends about 80 per cent of one's income on food, as does a sizable segment of mankind, a doubling in the price of wheat or rice cannot possibly be offset by increased expenditures. It can only drive a subsistence diet below the subsistence or survival level.

70. One reason it is possible for the world's affluent to ignore such tragedies is the changes that have occurred in the way that famine manifests itself. In earlier historical periods, famine was largely a geographical phenomenon. Whole countries or regions, whether Ireland or West Bengal, experienced dramatically high rates of starvation and death. Today, the advancements in national and global distribution and transportation systems have ensured that famine is generally more evenly spread among the world's poor rather than concentrated in specific locales. (The current

tragedy in sub-Saharan Africa is an obvious exception.) The modern version of famine does not often permit dramatic photographs, such as those of the morning ritual of collecting bodies in Calcutta during the Bengal famine of 1943, but it is no less real in the human toll it exacts.

#### A GLOBAL RESERVE SYSTEM

71. The global food outlook calls for serious consideration of the creation of an internationally managed food reserve system. Just as the United States dollar can no longer serve as the foundation of the international monetary system, so agriculture in the United States may no longer have sufficient excess capacity to ensure reasonable stability in the world food economy over a multiyear period.

72. World food reserves can be built up in times of relative abundance out of production surplus to immediate needs, and drawn down in times of acute scarcity. This would help to hold down price increases to the consumer during times of scarcity and to hold up prices to the producers during the inevitable periods of production in excess of immediate world demand. In effect, the cushion and stability that surplus agricultural capacity in the United States has provided for a generation would be provided at least partially by a world food reserve system. A system of global food reserves would provide a measure of price stability in the world food economy that would be in the self-interest of all countries. The world community, of course, also has a basic humanitarian interest in ensuring that famine shall not occur in the densely populated low-income countries following a poor crop year—an assurance the affluent countries may be less able to provide in the future if the current system of autonomous, nationally oriented food planning is allowed to continue without modification.

73. In 1973, A. H. Boerma, Director-General of the Food and Agriculture Organization of the United Nations (FAO), proposed a new system of internationally co-ordinated national food reserve policies. Under the FAO plan, all countries—both exporters and importers—would hold agreed minimum levels of food stocks. Governments would consult regularly to review the food situation, evaluate the adequacy of existing stocks and recommend necessary actions. The FAO plan received preliminary international approval at the FAO conference in Rome in November 1973.<sup>1</sup> If it is to be implemented effectively, the countries of the world must provide strong political and economic support in the coming year.

74. In the past, the United States has provided the world with safe reserve levels largely as a side benefit

<sup>1</sup> Report of the Conference of the Food and Agriculture Organization of the United Nations, Seventeenth Session, paras. 116-132.

of its domestic farm income programme. In the seller's market for food-stuffs which emerged in 1973, these reserves—both large grain stocks and idle cropland—were reduced substantially. Under such conditions, it would be highly unrealistic to expect the United States to bear the considerable expense of building grain reserves large enough to ensure world security. The FAO plan has the positive impact of spreading responsibility for reserve maintenance among both the exporting and importing countries of the world.

75. Under the FAO or any other world food reserve plan, special measures will be necessary to assist less affluent countries in establishing storage facilities and building up needed reserves. A new source of concessional assistance, perhaps in the form of an earmarked expansion of the soft-loan programme of the International Bank for Reconstruction and Development (World Bank), or a special fund within the FAO, will be necessary.

76. Prudence suggests that every effort be made to keep total world grain reserves of, at a minimum, 15 per cent of annual consumption. Historically, strong upward price pressures have developed when reserves have fallen below that level. At the current time, this would imply a need for about 180 million metric tons of grain held in reserves.

#### MODIFYING DIETS AMONG THE AFFLUENT

77. A variety of economic and moral forces may compel those in countries like the United States to reduce the demands they place on world food resources. This can most readily be accomplished through the substitution of vegetable-based protein for animal protein. Such a shift has already occurred in the substitution of vegetable oils for animal fats; in 1940, the average American was consuming 17 pounds of butter and 2 pounds of margarine; but by 1971, consumption averaged 11 pounds of margarine and 5 pounds of butter. Lard has almost been pushed off supermarket shelves by vegetable shortenings and a dominant share of whipped toppings and coffee whiteners marketed in the United States are now of non-dairy origin.

78. Technology for the substitution of vegetable for animal proteins has made considerable progress, mainly in the area of soya-based meat substitutes. Food technologists can now compress soya fibres into meat form; and, with appropriate flavouring and colouring, come up with nutritious substitutes for beef, pork and poultry. Soya protein "extenders", augmenting meat proteins in ground meats, are already in wide institutional use in the United States, and began appearing in supermarkets for general use in 1973. There are now good economic, ecological and nutritional reasons for reducing the average consumption of animal products in the United States. This fact should be reflected in governmental research budgets and in nutritional education programmes.

#### THE AGRONOMICAL POTENTIAL OF THE LESS AFFLUENT COUNTRIES

79. One of the most immediate means of expanding the food supply is to return the idle cropland in the United States to production, a process already in motion. Over the longer run, however, the greatest opportunities lie in the developing countries, where the world's greatest reservoir of unexploited food potential is located.

80. In those countries having the appropriate economic incentives, fertilizer, water and other required agricultural inputs and supporting institutions, the introduction of new wheat and rice varieties has increased production substantially. However, the recent jump in yields per acre in many developing countries appears dramatic largely because their yields traditionally have been so low relative to the potential. Current rice yields per acre in India and Nigeria still average only one third those of Japan; corn yields in Brazil and Thailand are less than one third those of the United States. Large increases in food supply are possible in these countries at far less cost than in agriculturally advanced countries if farmers are given the necessary economic incentives and have access to the requisite inputs.

81. When global food scarcity exists and the capacity of the international community to respond to food emergencies has diminished, a more convincing case than ever exists for strengthened international support of agricultural development in such populous food-short countries as Bangladesh, India, Indonesia and Nigeria. An almost equally convincing case can be made that in doing so, particular attention should be placed on effectively involving small farmers in the production effort. There is evidence that small-scale farmers, when they have effective access to agricultural inputs as well as health and education services, engage in labour-intensive agriculture and generally average considerably higher yields per acre than do large-scale farmers.

82. Concentrating efforts on expanding food production in the less affluent countries could reduce upward pressure on world food prices, create additional employment in countries where continuously rising unemployment poses a serious threat to political stability, raise income, improve nutrition for the poorest portion of humanity and, by improving social conditions, help create a climate in which birth rates will fall more rapidly.

83. A very encouraging recent development with special benefit for the developing countries was the formation in 1971 of the Consultative Group on International Agricultural Research. Headquartered at the World Bank in Washington, D.C., the Group is actively supported by the World Bank, the United States Agency for International Development, the Ford and Rockefeller Foundations, and several other Governments, foundations and international organizations. It is examining developing country research needs on a

systematic global basis and channeling financial support to priority areas.

84. The Consultative Group is co-ordinating the research efforts and funding of six key research centres in varied geographical regions and climates: International Wheat and Maize Improvement Centre (CIMMYT) in Mexico; International Rice Research Institute (IRRI) in the Philippines; International Centre for Tropical Agriculture (CIAT) in Colombia; International Potato Centre (CIP) in Peru; International Crops Research Institute for the Semi-Arid Tropics (ICRISAT) in India; International Institute of Tropical Agriculture (IITA) in Nigeria. The various donors allocated over \$24 million to these centres in 1973.

85. The Consultative Group represents an historic step in the evolution of a truly global agricultural research strategy. It is helping to rectify a serious deficiency of the past: the over-concentration of research efforts on the problems of temperate zone agriculture in the developed countries, often with little relevance for the needs of most of the developing countries.

86. Also encouraging has been the move to redirect aid efforts towards rural development and food production on the part of the World Bank, under its President, Robert McNamara, and of the United States foreign assistance programme under the terms of new legislation passed in 1973.

## WORLD POPULATION AND MINERAL RESOURCES: COUNTER-INTUITIVE OR NOT? \*

David B. Brooks and P. W. Andrews \*\*

1. One of the ironies of the limits-to-growth thesis is that, while purporting to present counter-intuitive ideas about the future of the world economy, it has accepted one of the oldest propositions of resource economics.<sup>1</sup> In its strongest form, this apparently common-sense proposition states that mineral resources will sooner or later run out, with drastic consequences for mankind. In a somewhat weaker form, it states that prices for minerals will rise sharply in the future. Much the same propositions are also put forward for energy and food supplies; but, as these topics are treated in other papers, the focus here is on non-fuel mineral resources.

2. The thesis of this presentation is that most assessments of mineral supply, including both optimistic and pessimistic assessments, are focusing on the wrong issue. It is the authors' contention that while it is naïve to jump from the premise that mineral resources are physically finite to the conclusion that this limits their economic availability, it is equally naïve to jump from the premise that mineral resources are economically infinite to the conclusion that they could be produced in enormous volume without major social or political problems. This statement takes this paper beyond the usual studies of resource availability, most of which stop when the case for availability is proved and place such implications as the effects on land use, the balance of payments and the international distribution of income beyond the scope of the analysis. Yet, the authors believe that these will prove less tractable than will the problem of supply itself.

\* The original text of this paper (E/CONF.60/SYM.III/7/Rev.1) was submitted to the Symposium on Population, Resources and Environment, Stockholm, 26 September-5 October 1973.

\*\* Respectively, Acting Chief, Mineral Economic Research Division; and Acting Head, Futures Research Section, Mineral Resources Branch, Department of Energy, Mines and Resources, Ottawa, Canada.

<sup>1</sup> The best known treatment is that of Donella H. Meadows and others, *The Limits to Growth: A Report for the Club of Rome's Project on the Predicament of Mankind* (New York, Universe Books, 1972), especially pp. 54-69. See also "Blueprint for survival", *The Ecologist* (London), vol. 2 (January 1972), pp. 1-43. For more technical treatment of minerals, see T. S. Lovering, "Minerals", in National Academy of Sciences, *Resources and Man* (San Francisco, California, W. H. Freeman, 1969); and Preston Cloud, "Mineral resources in fact and fancy", in William W. Murdoch, ed., *Environment: Resources, Pollution and Society* (Stamford, Conn., Sinauer Associates, Inc., 1971), pp. 71-88. For a quasi-official view of mineral supply, see United States of America, National Materials Advisory Board, *Elements of a National Materials Policy*, report NMAB-294 (Washington, D.C., 1972).

3. Most of this analysis is based on Canada or the United States of America, in part because information is more abundant on those countries, but also because both Canada and the United States are high-income, resource-rich regions that provide prototypes of what one must look for elsewhere in the world. The focus here is on the next 50-75 years, not on a more distant future when population will either have reached standing-room-only levels or population growth will have been completely curbed.

### MINERAL SUPPLY IN THE FACE OF GROWING DEMAND

#### *Mineral supply*<sup>2</sup>

4. Although the ideas of resource scarcity and abundance are deceptively simple, difficulties arise when one tries to transfer them from the individual to society. In a recent study, Fischman and Landsberg pose nearly a full page of questions that indicate just how difficult the concepts are to define. Notably, they ask:

"What is a 'shortage', and what is 'adequacy'? Is the supply of a given mineral 'adequate' only if it continues to be forthcoming in the 'required' amounts at present relative prices, or at prices rising no more rapidly than has been the trend, even if that trend reflects increasing supply stringencies? What if the only means of avoiding marked price change is the initiation of unaccustomed efforts at conservation, reuse, and recycling, or the making of major investments toward technological advance? Is adequacy measured in terms of current levels of minerals exploration, evaluation, and development, or trend levels? May a mineral be considered adequate just because it can be geologically inferred to exist in sufficient quantity, even if it takes major new outlays in exploration, evaluation, and development to find this quantity and get it into production?"<sup>3</sup>

<sup>2</sup> Much of this section is based on material presented in David B. Brooks, "Mineral supply as a stock", in William A. Vogely, ed., *Economics of the Mineral Industries* (New York, American Institute of Mining, Metallurgical and Petroleum Engineers, 1973) (in press); part of the material had previously been published in Canada, Department of Energy, Mines and Resources, Mineral Resources Branch, *Minerals: An Expanding or a Dwindling Resource*, Mineral Bulletin 134 (Ottawa, Canada, 1973).

<sup>3</sup> Leonard L. Fischman and Hans H. Landsberg, "Adequacy of non-fuel minerals and forest resources", in Ronald G. Ridker, ed., *Population, Resources and the Environment*, a report to the United States Commission on Population Growth

(Continued on next page)

5. These questions are not relevant exclusively to minerals. Such presumably renewable resources as fish and timber have been totally exhausted, while presumably non-renewable resources like minerals seem to be producible almost without end. In fact, analysts who have reviewed the issue carefully have not found many conceptual differences among natural resources on the basis of their renewability.<sup>4</sup> Nor have they been able to demonstrate any over-all tendency towards increasing scarcity (open space and timber are exceptions) in terms of higher real costs of production.<sup>5</sup> The way in which these general conclusions apply to minerals is examined below.

6. The literal notion of running out of mineral supplies is ridiculous. The entire planet is composed of minerals, and man can hardly mine himself out. Except for a few substances, notably crude oil and natural gas, which are discretely different from the rock masses that contain them, even the quantities of mineral materials in the upper mile of the earth's crust approach the infinite in size. A single cubic mile of average crystal rock contains 1 thousand million tons of aluminium, over 500 million tons of iron, 1 million tons of zinc and 600,000 tons of copper. Much the same sort of calculation can be made for sea water. This is not to suggest that such dilute materials will ever be mined, but only to indicate that exhaustion in a physical sense is meaningless.

7. Of more immediate interest is the fact that some of the elements that are most important to society are available in the greatest quantity. Copper and zinc are relatively rare metals. Iron and aluminium are not; together with a few other elements, they make up much of the crust of the earth; and there are thousands of square miles that could be considered low-grade iron and aluminium deposits, some of which will be mined in the future. Much the same can be said about phosphorus and potassium, the two critical mineral components for fertilizers.<sup>6</sup>

8. Further, there is a strong tendency for many mineral resources to increase in quantity as the quality that can be economically exploited goes down. In

general terms, this means that there is much more copper available at 0.5 per cent than at 0.6 per cent, more iron at 35 per cent than at 40 per cent, and so on. Exponential grade-tonnage curves have been drawn for manganese, aluminium, titanium, nickel, lead, zinc and columbium,<sup>7</sup> which indicates that this tendency is by no means confined to a few commodities, as is sometimes asserted.<sup>8</sup>

9. In short, almost every bit of available evidence indicates that vast quantities do exist of mineral resources that could be mined; and, further, that either as their price goes up or as their cost goes down (which is to say, as technology of extraction improves), the volume of mineable material increases significantly—not by a factor of 5 or 10 but by a factor of 100 or 1,000.

10. The real question, then, is not whether resources exist, but at what rate different sources of supply will become available to man in the sense of being economically feasible to recover. Natural materials do not become resources until they are combined with man's ingenuity. Over time, the record is impressive. Mineral resources have become more and more widely available despite (and partially because of) growing rates of consumption. This, in crude form, is the modern economic view of mineral resources, or the "cornucopian" view, as it has been dubbed.

11. Unfortunately, most descriptions of mineral resources include only the material that could be mined at today's prices and today's technology—what is properly termed "reserves"—and thus quite understate their availability.<sup>9</sup> The difference between reserves and resources becomes critically important when dealing with the so-called "life index", the ratio of the reserves of some element to its current consumption. The resulting figure is best regarded as a sort of inventory of stock on the shelf, so to speak, but it is sometimes mistakenly taken to mean the years remaining until exhaustion. In fact, the ratio tends to remain stable over time. As shown in table 1, mineral reserves in Canada have grown roughly in proportion to mineral production except in cases (asbestos and natural gas in the table) where structural changes were taking place in the industry.

12. With respect to the situation for the world as a whole, some data supplied by Preston Cloud are instructive in this respect, for, contrary to his emphasis, the authors find them reassuring.<sup>10</sup> On the basis of

and the American Future (Washington, D.C., Government Printing Office, 1972), p. 79. The approach and general conclusions of this study, probably the best of its kind, are summarized by Joseph L. Fisher and Ronald G. Ridker, "Population growth, resource availability and environmental quality", *American Economic Review*, vol. 63 (May 1973), pp. 70-87.

<sup>4</sup> A. Scott, *Natural Resources: The Economics of Conservation* (Toronto, University of Toronto Press, 1955).

<sup>5</sup> Harold J. Barnett and Chandler Morse, *Scarcity and Growth: The Economics of Natural Resource Availability*, for Resources for the Future (Baltimore, Maryland, Johns Hopkins Press, 1963). See also the brief discussion by Chandler Morse, *American Economic Review*, vol. 63 (May 1973), pp. 126-128.

<sup>6</sup> The case of phosphorus has become something of a *cause célèbre* after the publication of a report which states that phosphorus resources will be exhausted before the twenty-first century: Institute of Ecology, *Man in the Living Environment*, Workshop on Global Ecological Problems (1971). However, including only the already identified resources is sufficient to refute the Institute of Ecology figure: G. Donald Emigh, "World phosphate reserves—are there really enough?", *Engineering and Mining Journal*, vol. 173 (April 1972), pp. 90-95.

<sup>7</sup> The most extensive discussion of the application of grade-tonnage relationships to mineral resources is by Philip Musgrove, who prepared an appendix entitled, "Mathematical aspects of the grade-tonnage distribution of metals, to mineral resources as a stock", in David B. Brooks, *loc. cit.*

<sup>8</sup> Preston Cloud, *loc. cit.*, pp. 80-82.

<sup>9</sup> The terms "resources" and "reserves" are properly defined for minerals by J. Zwartendyk, *What is "Mineral Endowment" and How Should We Measure It?*, Mineral Resources Branch, Mineral Bulletin 126 (Ottawa, Canada, 1972).

<sup>10</sup> Preston Cloud, "Resource use and population pressure—the deadly exponentials", paper prepared for Columbia University/United Nations Conference on Development and the Environment, April 1972 (photo-copy).

TABLE I. CANADA: MINERAL RESERVES AND MINERAL PRODUCTION,  
SELECTED COMMODITIES, 1955 AND 1969

Mineral	Reserves			Production		
	1955	1969	Ratio	1955	1969	Ratio
Petroleum (thousand millions of barrels)	2.75	10.5	3.8	0.13	0.41	3.2
Nickel (millions of tons)	6.00	8.5	1.4	0.17	0.26 <sup>a</sup>	1.5
Copper (millions of tons)	14.50	22.9	1.6	0.33	0.61 <sup>a</sup>	1.8
Iron ore (thousand millions of tons)	5.28	33.0	6.2	0.01	0.04 <sup>a</sup>	4.0
Zinc (millions of tons)	20.4	34.2	1.7	0.43	1.16 <sup>a</sup>	2.7
Natural gas (million millions of cubic feet)	16.6	53.4	3.2	0.15	1.98	13.2
Asbestos (millions of tons)	86.0	1,200.0	14.0	1.06	1.61	1.5

<sup>a</sup> Data for 1968 used for comparison because 1969 was a strike year.

figure 1 (and other information), one foresees no problem to the end of the century in the economic availability of iron, manganese, silicon, aluminium, nickel and certain other materials, including energy minerals (taken together). These commodities include most of those upon which modern economic life is based.

13. One must consider, however, the generations beyond the end of the century; the question is whether there will be enough for them as well. Consider the record of the past 100 years, during which mineral supply has kept well ahead of long-term growth in mineral consumption. One may ask why a process of technological development that has been operating so well should come suddenly to an end. New developments will, of course, have to come more rapidly with higher rates of consumption, but it can be argued that the steepest exponential curve of all is the growth of human knowledge.

14. There are two main dimensions to the economics of future mineral availability:

(1) Geological extensions of supply through discoveries of new deposits and extensions of old ones;

(2) Technological extensions through the ability to work lower quality or less conventional materials.

In the authors' judgement, future increases in mineral supply will come more from the latter than the former dimension, and this outcome depends almost entirely upon the growth of knowledge. The distinction is important: a new discovery adds a new mine to the stock of resources; a new technology for lower quality resources can open up deposits across the world.

15. Therefore, it is simply not true, as is often remarked, that average rock will never be mined. As a matter of fact, in a few cases, commodities whose average grade in the ore deposit is lower than that in the crust are already being mined. (Titanium mined in beach sands is an example.) By exploiting technology as capital rather than the ore deposit (i.e., land) as capital, the very commonness of the rock may be most attractive. The more common the rock, the more

freedom one has to adjust the mine to the technology, rather than the other way around. In short, through modest advances in technology, mineral deposits become more rather than less available, and they can be mined in more rather than fewer regions.

16. Consider the case of nickel. Persistent price increases and generally rising world-wide demand for nickel are finally allowing the development of lateritic nickel deposits. These deposits are much more widespread than the sulphide deposits, typical of existing producing regions, and they are easier to mine. Until recently, however, there had been no commercially feasible way to extract the nickel from them. Judging from the success of several laterite mines in third world countries, this is no longer a problem. As a result, world nickel reserves have been augmented by many times, and the nickel-mining industry will be less concentrated geographically and industrially.

#### Mineral demand

17. Studies published in the past few years have, without exception, indicated an increasing demand for mineral commodities in the future, mainly from the countries that are already industrialized, but also from those countries in the process of industrializing.

18. The most comprehensive recent set of mineral forecasts is that made by the United States Bureau of Mines.<sup>11</sup> World demand for primary, non-energy minerals was based on contingency forecasts and predicted a spread of growth rates from 3.8 to 5.6 per cent per annum. Demand in the United States of America was based on specific forecasts of growth of population and of gross national product (GNP) and predicted a spread of growth rates from 4.2 to 6.0 per cent per annum. Some specific forecasts for the United States are given in table 2.

<sup>11</sup> United States of America, Department of the Interior, Bureau of Mines, *Mineral Facts and Problems, 1970* (Washington, D.C., Government Printing Office, 1970).

TABLE 2. UNITED STATES OF AMERICA: DEMAND FOR PRIMARY REFINED METAL, 1968 AND 2000 (Millions of metric tons)

	1968	2000		
		Low	Medium	High
Copper	1.40	4.40	5.80	7.20
Lead	0.80	1.20	1.90	2.50
Zinc	1.30	1.90	2.80	3.60
Manganese	1.00	1.70	1.90	2.10
Nickel	0.15	0.35	0.42	0.50
Aluminium	3.20	15.70	23.40	31.20

SOURCE: United States of America, Department of the Interior, Bureau of Mines, *Mineral Facts and Problems, 1970* (Washington, D.C., Government Printing Office, 1970).

19. Another major study of mineral demand to the year 2000 (for the United States only) was made by Resources for the Future, using an input-output model together with various assumptions of population growth and productivity change.<sup>12</sup> Some of these results, which tend to be lower than those of the Bureau of Mines, are shown in table 3.

20. Using a method that was apparently first developed by the International Iron and Steel Institute (IISI),<sup>13</sup> the Mineral Resources Branch in Canada has

<sup>12</sup> L. L. Fischman and H. H. Landsberg, *loc. cit.*

<sup>13</sup> International Iron and Steel Institute, Committee on Economic Studies, *Projection 85: World Steel Demand* (Brussels, March 1972).

TABLE 3. UNITED STATES OF AMERICA: DEMAND FOR CERTAIN METALS IN 2000

(Millions of metric tons)

	Low population		High population	
	Low growth	High growth	Low growth	High growth
Copper .....	2.6	3.3	2.9	3.6
Lead .....	1.5	2.0	1.8	2.2
Zinc .....	2.8	3.5	3.2	4.0
Manganese ...	1.9	2.4	2.2	2.6
Nickel .....	0.29	0.36	0.33	0.40
Aluminium ...	11.9	14.5	13.0	15.9

initiated still another set of projections. This method, referred to as "intensity-of-use analysis", predicts that demand levels may be lower in the year 2000, at least in industrialized countries, than do most other projections. Similar results have been obtained in the study recently released on behalf of the United States National Commission on Materials Policy.<sup>14</sup>

21. The intensity-of-use approach combines both time-series and cross-sectional information. For each country, the quantity of some material used per unit of national product (its intensity of use) is plotted against *per capita* income. The IISI study showed that, as *per capita* income increases, the intensity of steel use at first rises but then peaks and begins to decline. Absolute consumption of steel continues to increase because the decline in intensity is more than overcome by the increase in gross national product, but the increase in consumption is less than is forecast by trend analysis. The level of income at which the intensity

<sup>14</sup> Wilfred Malenbaum and others, *Material Requirements in the United States and Abroad in the Year 2000*, a research project prepared for the National Commission on Materials Policy (State College, Pa., University of Pennsylvania, 1973).

peak was reached varied by country, but it was close to \$3,000 *per capita* for most Western industrial countries.

22. When this method was applied to non-ferrous metals, similar peaked patterns were observed. Figure II shows some typical results for primary copper and aluminium. Copper data for Canada and the U.S. (plus Japan for purpose of illustration) were plotted for 1926-1971, long enough to show clearly the rise and decline in intensity. (A shorter data base was used in the study prepared for the U.S. National Commission on Materials Policy; hence, the patterns are less clear.) Intensity of use of copper in the United States fits the "ideal" shape, with the maximum occurring during the Second World War. In Canada, there was no fixed pattern prior to 1940; but after the Second World War, a clear decline commenced, although with waves corresponding to the major post-war business cycles. The position of the Canadian curve above that for the United States probably reflects the export orientation of the Canadian economy, since intensity of use is measured by shipments from refineries.

23. The implications of declining intensity of use can be seen by further considering copper in the United States of America. Figure II shows that the curve peaked at nearly 4 metric tons at between \$1,700 and \$1,800 *per capita* (1961 dollars) in the late 1920s and again in 1940. Ignoring the distortions of the Second World War, the curve declines fairly uniformly to slightly over 2 metric tons at \$2,800 *per capita* from 1959 to 1961, and then fell more slowly in the following decade to just below 2 metric tons at \$5,700 *per capita*. If any decline continues, there are important implications for projections of consumption. The projections of gross national product and population growth used by the Bureau of Mines indicate that an income *per capita* on the order of \$7,000 (1961 dollars) can be

Figure II. Intensity of use of copper and aluminium: examples from Canada, Japan and United States of America

SOURCE: Canada, Department of Energy, Mines and Resources, Mineral Resources Branch.

expected in the United States by the year 2000. At that level, consumption of copper could be:

(a) At 2.0 metric tons per \$1 million of gross national product (GNP), 4.9 million metric tons;

(b) At 1.5 metric tons per \$1 million of GNP, 3.7 million metric tons;

(c) At 1.0 metric tons per \$1 million of GNP, 2.7 million tons.

The Bureau of Mines median contingency forecast is 5.8 million metric tons.

24. The situation with respect to aluminium is more difficult. Its intensity-of-use curve is still rising in the United States, but the rate of increase has recently declined. The dashed lines in figure II represent three possible directions the intensity of use for aluminium might take in the United States. By the end of the twentieth century, they are equivalent to consumption levels of 7.3 million, 16.5 million and 22.2 million metric tons, which can be compared with the median forecast by the Bureau of Mines of 23.4 million metric tons.

25. These notes on future mineral demand only indicate that, as countries move into a post-industrial phase, their intensity of use of mineral commodities tends to decrease. The pattern for the currently less industrialized countries is not as clear, and other variables would have to be studied before sound comments could be made on total world demand. However, it does not appear likely that non-energy mineral consumption will continue to grow at the rates at which it has in the past.

#### *The challenge to "cornucopianism"*

26. The idea that mineral supplies could be greatly augmented by technology has always been challenged by certain geologists. Recently, their views have been seconded by some systems analysts. Several of the conceptual and empirical aspects specifically related to minerals can be dealt with fairly quickly here.<sup>15</sup>

27. The challenge based on geological evidence has several strains. First, some analyses depend upon extrapolation of production trends along mathematical curves. However, production history is not based solely on the geologically available supply, but also on such institutional factors as military policies and the tariff structure. Secondly, other analyses are based on either individual mines or types of ore deposits that are

<sup>15</sup> D. H. Meadows and others, *op. cit.*, provides the best example of the challenge from the systems analysis point of view, while the chapters by T. S. Lovering, *loc. cit.*, and by P. Cloud, "Mineral resources in fact and fancy", *loc. cit.*, provide the best examples of the challenge from a geological point of view. The geological challenge is criticized at length by David Brooks, *loc. cit.* The limits-to-growth thesis has stirred considerable debate. See, for example, the Consultative Assembly of the Council of Europe, *Report on The Limits to Growth*, including articles by Aurelio Peccei and Manfred Siebker (pro) and J. Maddox (con), document 3233 (22 January 1973). With respect to minerals in particular, William Page, "The non-renewable resources sub-system", *Futures*, February 1973, pp. 33-42.

characterized by sharp cut-offs between ore and country rock. Unquestionably, mines and such ore deposits can be exhausted, but this does not prove that world supplies are declining in an economically meaningful sense. Thirdly, still other analyses are based on questionable ideas about the economics of discovery. While exploration costs more now than formerly, this factor is irrelevant. What is important is the cost per unit of information gained, and eventually of ore discovered, and this cost is not increasing inordinately.<sup>16</sup> Moreover, it is hardly surprising that many deposits coming into production today were discovered years ago, for today's exploration is also turning up numerous deposits that will not be mined for some years.

28. Turning to the challenge deriving from systems analysis of the limits-to-growth type, the first comment is that it mistakes both the nature of and the evidence concerning resource supply. Minerals are treated as if they came from a fixed stock, an approach that is not improved by qualifications that the reserve figures are perhaps off by a factor of five or ten. This merely compounds the confusion, for one is really dealing with a flow, not a stock, and with a flow that responds to demand. True, one may have witnessed a long-term increase in the price of copper over the past 10 years, though institutional factors have obviously played a role as well. And for some commodities, perhaps tungsten, real shortages may develop.<sup>17</sup> However, such exceptions are far from proving that prices for many minerals will increase exponentially in the future under consideration here.

29. Secondly, the effectiveness of a price-cost system in altering the quantities demanded and supplied is ignored. Surely one cannot reasonably assume that mineral prices will continue to rise but that this will have no stimulating effect on exploration, technological development and recycling (to say nothing of a damping effect on demand). Nevertheless, this assumption is made, leaving the authors open to the criticism that they did not deal with what, for all of its defects, is an effective and efficient adjustment mechanism (and one that can be applied whether the price derives from a market in a free enterprise system or from a central bureau in a centrally planned economy).

30. Lastly, the nature of demand is also mistaken. While dramatically increasing demands have been seen over the past several decades, this does not mean that such increases have been or will continue to be exponential. As shown above, more sophisticated analyses suggest that relative demands decline, after a point, with increase in *per capita* income. Indeed, even though absolute increases in quantities demanded are still enormous, relative growth is sufficiently damped for one study to suggest that mineral production will need to grow less rapidly in the future than it has grown in

<sup>16</sup> D. A. Cranstone and H. L. Martin, "Are ore discovery costs increasing?", *Canadian Mining Journal*, vol. 94 (April 1973), pp. 53-64.

<sup>17</sup> L. L. Fischman and H. H. Landsberg, *loc. cit.*, p. 93.

the recent past, exactly the opposite of most conclusions based on trend analysis.<sup>18</sup>

31. The foregoing points combine to cast considerable doubt on the whole idea that mineral resources will limit growth. For the model itself, this creates a very weak link in the causal chain.<sup>19</sup> Thus, one must ask whether anything new has been learned from recent challenges to "cornucopianism"? The authors' conclusion is that nothing new has been learned, but that people have been reminded to ask some important questions.

#### SOME IMPLICATIONS OF HIGH RATES OF MINERAL SUPPLY AND DEMAND

32. The first section of this paper concludes essentially that minerals can be made available (at prices not greatly different from current prices) to satisfy demands that are growing because of population growth, higher *per capita* incomes and changing technology. Rather than focusing on physical or economic availability, this section assumes that these minerals are produced and questions some of the implications of producing them.

#### *Pollution*

33. Perhaps the most widely recognized undesirable impact of higher rates of resource production and consumption is pollution. In saying this, the authors are well aware that major improvements in pollution technology can be expected, so that mines and smelters will produce less effluent per ton of production, transport facilities will spill less per ton-mile etc. However, to obtain a significant improvement in the environment, such steps are not sufficient. The decrease in effluents per unit of production or of consumption must more than overcome the increase in production or consumption itself. Moreover, as scale of production increases, so does the impact of any miscalculation or accident (which is inevitable). Thus, one can either strive continually for technologies that will so reduce pollution as to permit safe production (and consumption) of whatever is wanted or one can reduce growth to make the technological task of environmental improvement less expensive and less frenzied.

34. There are two additional aspects of pollution that are less amenable to technological solutions: the chronic low-level exposure to pollutants that is all but inherent in an industrial world; and the possibility of triggering an ecological catastrophe.

35. Much pollution-control practice has been based on the theory that there are "thresholds" below which health effects do not occur. It is now known that, for many pollutants, including radio-activity and lead,

thresholds do not exist. Chronic low-level exposure is important; for every addition of such pollutants, someone's life is shortened or days of sickness lengthened.<sup>20</sup> Since some escape of such substances cannot be avoided, the greater the amount of them introduced into the environment, the less human life is implicitly valued.

36. At the other end of the probability scale, it is conceivable that man could touch some physical or biological lever that will prove globally catastrophic. Fortunately, such problems are less likely to derive from non-fuel minerals than from energy production and consumption. Even the more difficult problems, acid mine drainage and smelter-based SO<sub>x</sub>, tend to be local or regional in scope rather than national or international. Nevertheless, however small the probabilities, they bear close surveillance as part of the Earthwatch programme which was initiated at the United Nations Conference on the Human Environment, held at Stockholm, 1972.

#### *Extensive land-use change*

37. In speaking of pollution, reference has been made to effluents added to air, water or soil. Somewhat different, but at least as much at issue in many mining regions, are the land-use changes that will be necessary if higher rates of production are to be achieved. For example, the surface-mining debate in most places is much more a question of appropriate land use than it is of pollution.

38. However, given that resources are irregularly distributed, the demands for efficiency and for large-scale production will dictate that resources be produced wherever they are found, and by low-cost methods. Land for ecological preserves, recreation and agriculture is likely to take second place to demands for land to be used in mineral production. For example, resources located in the Arctic or other untouched areas will have to be extracted, as will deposits of common materials (sand, gravel, rock) located near urban areas. Moreover, the production goal will be to economize on manpower and materials, and perhaps on energy, but at the expense of consuming, and sometimes irreparably altering, the land surface. Such tendencies will be aggravated because, as grade becomes lower, more and more mining is required to recover the same volume of valuable metal or mineral. Thus, one has the proposals for using nuclear energy to fracture underground ore bodies or to remove the overburden from near-surface ones.<sup>21</sup> The very scale of such an effort, coupled with the need to isolate large areas from entry for reasons of safety, implies enormous land-use change.

<sup>18</sup> W. Malenbaum and others, *op. cit.*, pp. 38-40.  
<sup>19</sup> This point is made forcefully by John S. Carman, in his comments (unpublished, 1972) on the report of the Club of Rome entitled "Limits to Growth". See also, W. Page, *loc. cit.*, p. 41.

<sup>20</sup> National Academy of Sciences, National Academy of Engineering, *Man, Materials and Environment*, a report for the National Commission on Materials Policy (Cambridge, Mass., Massachusetts Institute of Technology Press, 1973), pp. 71-80.  
<sup>21</sup> David B. Brooks and John V. Krutilla, *Peaceful Use of Nuclear Explosives: Some Economics Aspects*, for Resources for the Future (Baltimore, Md., Johns Hopkins Press, 1969).

39. Most land-use changes under discussion here cannot be solved technologically. While some effects can be mitigated (underground quarries near urban areas, surface reclamation), many land-use decisions are all but irreversible and "simply" involve questions of value.

#### *Increased energy consumption*

40. Another penalty of going to lower grade ores is the need for higher rates of energy consumption per unit of output (because there is less valuable material per ton). This energy penalty is still higher since some of the new sources require finer crushing or are more refractory,<sup>22</sup> though this effect is commonly offset in part by reduced requirements for energy in mining (as with the laterite nickel ores described above).

41. Having recognized this problem, however, there is relatively little more to be said. On the one hand, if energy costs go up, as they seem likely to do, technology will turn towards cheap sources of energy and to ways of conserving energy in production just as it has heretofore conserved labour. The use of nuclear explosives described above is an example, for it offers a relatively inexpensive and efficient way of using energy in mining.

42. On the other hand, it seems a little ridiculous to point to mineral production as a cause of such global problems as changes in heat balance or climate. Mineral production is responsive to, not creative of, demand for consumption, and by about the end of the time frame under consideration here, the world must have found a way to deal with this energy problem in the widest sense.<sup>23</sup>

#### *Instability in human settlements*

43. The expansion of mining is closely connected with certain problems of human settlements. The broadest issue is that the introduction of mining can be a sociological shock. For example, one of the objections to proposals for copper mining in Puerto Rico is based on the cultural change that it would impose on a rural and largely self-sufficient region.<sup>24</sup> Much the same objection has been raised with respect to Eskimos in northern Canada. Even less than land use can these issues be resolved technologically. Most often, they require all-or-nothing decisions based on the values of the society.

44. Most mining communities, and all those which cannot eventually find an alternative economic base, have a limited life. Moreover, few of them have been attractive places in which to live; in many instances, they were treated as "camps" to be abandoned as soon as the mine was closed, or they were built as oppressive

company towns. Even if, in most countries, mining communities are currently more carefully planned, their inherent tendency to deplete their reason for existence cannot be ignored, for the result is often a depressed region with high unemployment and few services. Such problems are intensified by the cyclical nature of mineral investment, so that there tend to be cycles, some 20-40 years later, during which a country is faced with waves of mine closures.

#### *International distribution of income*

45. In stating that the supply of mineral resources is unlimited, the authors deliberately made no distinction between the industrial and the non-industrial worlds, because there is enough for all. However, contrary to what one might expect, increased competition for minerals is likely to work against, rather than for, primary producing countries. If, as has been assumed, the increasing production-consumption trends of the past are going to continue, it seems excessively heroic to assume at the same time that the future distribution of returns is going to be very different.

46. There are several bases for this assertion. First, linkage effects from mining to other sectors of the economy are relatively weak. A mine alone, or even a mine associated with a smelter and refinery, does not confer large benefits upon a society in terms of direct or indirect employment and income effects—unless manufacturing industry is built upon the resource base.<sup>25</sup> In fact, most development economists now believe that natural resource development is more often the result of activity in other sectors of the economy (or other regions of the world) than a source of development itself.<sup>26</sup> For example, Chilean economists have pointed out that most of the railway system of that country, extensive though it is, was designed to move copper from mine or smelter to port and does little to stimulate development or to integrate the country.

47. Secondly, even the greater opportunities to collect economic rent that increased competition for resources offers is very qualified. The Organization of Petroleum Exporting Countries (OPEC), whose members constitute the major oil-exporting countries, has succeeded in raising oil prices and national revenues. But OPEC remains a unique example, successful because of the military and commercial demand for petroleum, the difficulty of storing it and the concentration of production in a region with a

common ethnic background. Moreover, substitution possibilities are generally broader for other mineral commodities than they are for petroleum—and they are continually broadened through technology. Technology points to ways to utilize lower quality and, hence, more widely occurring, mineral resources (as with taconites); it also shows how to use more common materials in place of rarer ones (as with ceramics and plastics to replace metals). Both results favour industrialized regions, where, of course, most of the research is funded. Therefore, while serious efforts are under way, notably among copper- and iron-ore producing countries, to gain more revenue, the question of how far the OPEC model can be effectively copied is an open one.

#### CONCLUSIONS

48. With respect to mineral supplies, world population and world income can grow at any likely rate for the next 50 or 75 years, and probably for longer. This cannot be done, however, without environmental costs, without affecting the development of countries in the third world and, perhaps most important, without ignoring the critical questions of power. In what might be termed the revisionist form of the limits-to-growth thesis, Aurelio Peccei and Alexander King, co-founders

of the Club of Rome, appear to be saying that the forecasts of doom themselves are unimportant, but that they symbolize critical problems of the nature and uses of power in the modern world:

“... the Club of Rome is questioning the quality of growth and its distribution around the world. . . . We know that the present structure of the world is obsolete. . . . Both private and state capitalism are stale . . . we have to develop something else.”<sup>27</sup>

49. Surely, continually increasing rates of mineral production are symptoms of this obsolete power structure, a result of the fact that, ultimately, population growth and monetary income growth lead to demands for natural resources that necessitate their being found and produced regardless of the implications. Since such higher rates of production are geologically and economically sustainable, mankind should choose among alternative paths of growth, and hence among alternative rates of mineral development, according to what is liked or disliked about these implications. The key information will not be found in tables comparing reserves and consumption, but in preferences and ethics.

## NATURAL RESOURCE ADEQUACY AND ALTERNATIVE DEMOGRAPHIC PROSPECTS \*

Ronald G. Ridker \*\*

1. A long-term assessment of resource adequacy is important as a basis for establishing the proper sense of the urgency with which the population problem should be viewed, but it is a difficult topic because of the lack of knowledge about the material content of vast regions of the earth and about the nature and timing of future technological developments. To make a proper assessment one should be able to answer such questions as whether fusion reaction will be harnessed for large-scale production of electricity before the earth's supplies of fossil fuels become seriously depleted. But these questions are basically unanswerable and will probably remain so for the foreseeable future. All one can hope to do is provide a framework for thinking about these issues and a perspective that may be helpful in coming to some tentative, interim conclusions.

2. This paper attempts to do so by discussing the following four questions:

(1) The degree to which natural resources are important for economic development;

(2) Given the economic and population growth that has occurred during the past century, whether there is any indication that natural resources have become scarcer;

(3) Whether there are any indications that natural resources will become significantly scarce—that the world or major parts of it are likely to “run out” of important resources—in the future;

(4) Determination of the role that population growth, as opposed to other factors such as economic growth, plays in this process.

Of necessity, the answers provided are based on a number of very simplifying assumptions, but, it is hoped, assumptions that are useful in deriving implications for population policy. Environmental considerations, while important, were the subject of the Third Symposium on Population, Resources and the Environment, held at Stockholm from 26 September to 5 October 1973, and therefore will not be covered in detail.

\* The original text of this paper (E/CONF.60/SYM.1/30) was submitted to the Symposium on Population and Development, Cairo, 4-14 June 1973; and to the Symposium on Population, Resources and Environment, Stockholm, 26 September-5 October 1973.

### ROLE OF NATURAL RESOURCES IN ECONOMIC DEVELOPMENT

3. No one would deny that enormous quantities of natural resources have been consumed in the course of the development of the developed countries, and that with only modest variations this pattern will repeat itself to the extent that economic development is achieved in developing countries.<sup>1</sup> While not sufficient, land and natural resources are certainly necessary conditions for development, just as are inputs of labour, capital and technical knowledge. But beyond these obvious points, there is considerable controversy. On the one side are those who argue that resources are of relatively little importance for development except in so far as they determine its direction. On the other side are those who emphasize the importance of climate, accessibility (a mixture of geographical location, topography and transportation technology), or one or another industrial resource, such as coal or iron.

4. Those who argue that resources are relatively unimportant to development begin by asserting that every country has the minimum necessary amounts of natural resources, and that what developing countries lack is the socio-technical knowledge and capital base necessary to take advantage of these resources.<sup>2</sup> This point of view is supported by showing that little, if any, correlation exists between incomes *per capita* and amounts of arable land or natural resources *per capita* in different countries. There are developing countries with rich resources and developed countries with poor resources; but there are no developed countries without a good socio-technical and capital base.

5. The explanation for this situation is the extent of the substitutability in both production and consumption that is possible among natural resources and between them and other inputs, including skills and organizational arrangements. Labour and capital can be substituted for land in the production of food to the extreme extent of using hothouse methods of production, animal power can be substituted for petroleum

<sup>1</sup> One likely variation is a lower materials content to the gross national product, since poor countries may be able to skip technological stages, going directly to materials-consuming methods. Another variation is in life-styles which might be less materials-using at the same income levels. But it is very unlikely that such differences would significantly alter the role played by resources in development.

<sup>2</sup> Simon Kuznets, *Towards a Theory of Economic Growth* (New York, W. W. Norton and Co., 1968), pp. 30-31.

in transportation systems and both forms of energy consumption can be reduced substantially through organizational arrangements and urban designs that minimize the need for private transportation. Moreover, fresh water can be collected from rain, rivers, lakes and underground sources or produced with energy and capital through desalination. A crude index of such variability in practice is provided by comparing the amounts of minerals used in producing a dollar of output in different countries. As can be seen in the following table, such use varies among groups of countries by as much as four times. But the most important source of substitution possibilities arises from international trade, which permits a country like Japan, which possesses no iron ore, to become one of the most intensive users of this resource.

SELECTED COUNTRIES AND RESOURCES, THOUSANDS OF METRIC TONS USED PER THOUSAND MILLION DOLLARS OF GROSS DOMESTIC PRODUCT, 1966-1969

	Iron ore	Primary aluminium	Total energy (coal equivalent)
United States of America . . . . .	76	3.480	2,070
Western Europe . . . . .	107	2.470	1,420
Japan . . . . .	217	3.120	1,290
Latin America . . . . .	53	0.850	1,190
Asia . . . . .	33	0.830	980

SOURCE: "Materials requirements in the United States and abroad in the year 2000", a research project prepared for the National Commission on Materials Policy by The Wharton School, University of Pennsylvania, March 1973, under the direction of Wilfred Malenbaum.

6. An important implication of this argument for population policy is that one cannot easily classify countries as overpopulated or underpopulated by comparing the amounts of arable land or natural resources *per capita* that they possess. Not only is there a serious problem of controlling for variations in productivity resulting from differences in types of soils, rainfall and water supplies, climate, accessibility and richness of ores but one of controlling for differences in the capacity to utilize existing resources and the capacity to substitute for scarce domestic resources, either through changes in the production and consumption functions, or through international trade.

7. One cannot say, for example, that despite its potentially large resource base and low population densities, Brazil is underpopulated in relation to Japan. It would be wrong to say this because of the greater capacity of Japan to extract, acquire and substitute for the land, minerals and fuels with which it is poorly endowed on a *per capita* basis. To say that Brazil is underpopulated in relation to Japan, one must argue that the population densities of Brazil with respect to land and natural resources will remain favourable when it has acquired the same socio-technical capacity that Japan currently has. But the development of such capacity takes time; if current rates of population growth and

resource exploitation continue in Brazil, the outcome is not at all clear.

8. It may be asked if natural resources are that unimportant. Surely, countries with more natural resources are better off than those with less, indeed, in large measure just because a rich resource base can be used to build or buy the technology and capital necessary to take further advantage of that base. Substitution possibilities can be exaggerated, especially for countries that lack the income, knowledge and capital necessary to make the substitutions; and even developed countries may not be able to develop alternatives quickly enough, if a number of shortages occur at once in a brief period of time.

9. Furthermore, while international trade permits some countries to compensate for the natural resources they lack, it cannot similarly compensate for a world-wide shortage. To put it differently, it must be asked how many countries could simultaneously follow the route taken by Japan and the Netherlands, of trading their technological and organizational abilities for resources, before the basis for this trade would be destroyed; that is, whether the high level of living of such countries is dependent upon the existence of less industrialized developed countries with little else than natural resources to trade.

10. It is, therefore, to be concluded that the argument that resources are unimportant applies only to developed countries, and then only in a world of relative abundance or when sufficient time is available to develop alternatives. In the other four fifths of the world, which currently lacks the capital, drive, skills and institutions necessary to compensate for the niggardliness of nature, the presence or absence of adequate supplies of natural resources on a *per capita* basis can mean the difference between development and no development.

#### NATURAL RESOURCE ADEQUACY IN HISTORICAL PERSPECTIVE

11. If the world's resource base is being depleted, resource prices, in relation to those of labour, capital and finished goods, should be increasing; but there is little, if any, historical evidence to suggest that this is the case. Indeed, one of the most comprehensive studies<sup>3</sup> of this issue undertaken to date—one that looks at statistical evidence from the United States of America for the period 1870-1957—suggests the opposite: not only have relative prices of natural resources fallen, but the cost of extractive output in relation to that of total output has decreased during this period. The explanation for this phenomenon is to be found in a variety of factors, including shifts in demand from less plentiful to more plentiful resources,

<sup>3</sup>Harold J. Barnett and Chandler Morse, *Scarcity and Growth: The Economics of Natural Resource Availability, for Resources for the Future* (Baltimore, Maryland, Johns Hopkins Press, 1963).

technological advance in conversion and extraction, and new discoveries within the United States of America. Increases in imports as a means of keeping prices down were not very important, according to the authors of this study. A more recent study,<sup>4</sup> which follows the same statistical series up to 1969, indicates that, in general, these prices and costs have continued downwards, but, depending upon how much weight one gives to recent years, may be bottoming out. Long-term studies of the terms of trade between raw materials and manufactured goods in international trade tends to support these findings. Unfortunately, however, similar studies for other countries do not appear to be available.

12. This finding for the United States of America is not very surprising. All it says is that new discoveries and technological developments permitted supplies of raw materials to grow at least as rapidly as demand during this historical period. It says little about the world as a whole and nothing at all about the distribution among countries of resources and incomes, which became more unequal during the period under review. Most important, the finding says nothing about the future, but it should at least give one pause before assuming without further study that the world is obviously heading into an era of growing resource scarcity.

#### RESOURCE ADEQUACY IN THE FUTURE

13. Whether resources will be adequate in the future or not depends in large measure upon the time horizon. If population and material economic growth were to continue without abatement, and if one rules out the possibility of importing materials and energy from outside the earth (or exporting people) on an ever-increasing scale, it is certain that the earth would eventually run out of resources, environmental carrying capacity or space. The second law of thermodynamics, the entropy law, makes this quite certain. Indeed, this same law makes it certain that even a constant rate of economic activity cannot be maintained forever, unless that level of activity is sufficiently low to permit mankind to live within the limits imposed by the flow of solar energy he is able to tap.<sup>5</sup> Technological

<sup>4</sup> Study being undertaken by Professor Robert Manthey, Michigan State University, East Lansing.

<sup>5</sup> The qualification is important, for the amount of solar energy received by the earth is enormous in relation to terrestrial stocks of energy. Hard to believe though it may be, the entire terrestrial stock of energy is estimated to be equal to only four days of sunlight. In principle, this could permit man to live for another 5 thousand million years (the remaining estimated active life of the sun) at a reasonably high level of living, provided population growth ceased during the next century. But as a practical matter, with technologies and ways of life one can imagine evolving and spreading throughout the world in the foreseeable future, this indefinitely sustainable level of living is probably significantly below the level at which most of humanity exists today. A fascinating discussion of these issues can be found in N. Georgescu-Roegen, *The Entropy Law and the Economic Process* (Cambridge, Mass., Harvard University Press, 1971).

breakthroughs may make it appear to be possible to continue growth forever. But this illusion arises from man's myopia. Scientific knowledge can only postpone the consequences of the laws of nature, it cannot repeal them. No matter how closely one may approach it, there is no such thing as a perpetual-motion machine.<sup>6</sup>

14. But knowledge that growth must eventually cease is of no practical significance as such. One may ask how much time mankind has. If mankind has from hundreds to thousands of years, as the technological optimists believe, there is room for non-resource considerations to play an important role in determining how forcefully measures to limit growth are applied. In this case, it is easy to imagine policy-makers deciding to continue to encourage economic growth, while limiting family planning activities to helping parents reduce the gap between desired and actual family size. On the other hand, if the people on this earth, or at least on parts of it, have no more than from 50 to 150 years before exhaustion of resources is approached, as those who argue against reliance on technological "fixes" and new discoveries maintain, far more stringent policies are called for.

15. Two studies, taken together, can be used to shed at least some light on this question. One is the comprehensive review of projected world-wide demands and estimates of reserves for individual natural resources undertaken by the United States of America, Bureau of Mines, in 1970,<sup>7</sup> and the other is a study of the United States undertaken by Resources for the Future (RFF).<sup>8</sup> Concentrating on the next half a century, these projections can be characterized as free from surprises and conservative in the sense that they assume no significant changes in tastes, technology, institutions or relative prices, and fairly rapid increases in population and economic growth. Demand for the rest of the world is based, more or less, on an extrapolation of trends in consumption during the past two decades, while that for the United States is derived from a dynamic input-output model of that economy. Reserve estimates incorporate the judgement of experts about the world's "known and potential reserves", a term that includes "concealed deposits for which there is specific geologic evidence and for which the specific

<sup>6</sup> Another often-mentioned reason why growth must eventually stop is environmental deterioration. But in the final analysis it is a question of the availability of energy in useful forms, for with it, man can treat, move or protect himself from pollution and environmental deterioration. Even space can be increased with sufficient energy, by building upwards and outward. A limitation on the use of energy could be the buildup of waste heat. But this depends upon the source of energy and the efficiency with which it is utilized. To the extent that reliance is placed on geothermal heat and energy from the sun, a serious buildup of heat need not occur.

<sup>7</sup> United States of America, Department of the Interior, Bureau of Mines, *Minerals Facts and Problems, 1970* (Washington, D.C., Government Printing Office, 1970).

<sup>8</sup> Ronald G. Ridker, ed., *Population, Resources and the Environment*, vol. III of Commission research reports of the Commission on Population Growth and the American Future (Washington, D.C., Government Printing Office, 1972).

location can be described", but which "makes no allowance for ore in unknown structures or undiscovered districts", or for "paramarginal and sub-marginal reserves" which would require sizable increases in prices to be considered commercially valuable.<sup>9</sup>

16. Of the 19 non-fuel minerals reviewed in the RFF study, world-wide reserves as now estimated appear inadequate to meet the "high" projections of cumulative demand between now and the year 2000 in the cases of aluminium, lead, zinc, tungsten and sulphur. By 2020, copper, manganese, nickel, molybdenum and titanium would be added to this list. For example, world-wide consumption of copper, estimated at 7.4 million tons in 1968, is projected to be from 20 million to 39 million tons in 2000 and from 37 million to 116 million tons in 2020 (the differences between the high and low numbers indicate how poor these estimates are); or in cumulative terms, from 792 million to 1,180 million tons for 1968-2000 and from 2,277 million to 4,974 million tons for 1968-2020. By contrast, the world's principal commercial resources of copper, in metal content, is estimated at 808 million tons.

17. But the significance of these findings differs considerably among minerals. Only modest price increases would be necessary to turn a deficit of sulphur and aluminium into a surplus. In other cases, somewhat greater increases in prices, sufficient to increase exploration and stimulate some substitution and additional recycling, would be necessary to close the gap between demand and supply. The most serious case is tungsten, for which it is difficult to establish a reserve picture that promises adequacy; here, main reliance might have to be placed on technological changes that permit the gradual phasing-out of this metal in applications that can use, though perhaps at higher cost, substitute materials and processes.

18. World energy demand and supply projections depend so heavily upon the technological changes that projections in this case have been limited to the year 2000. For that period, fossil-fuel reserves appear quite adequate to meet the expected fourfold increase in demand, even without including oil in shale and tar sands. Nuclear fuels also should be adequate, particularly if breeder technology is fully developed. But the situation is not quite so favourable when environmental problems are included, problems that pervade all stages of energy use, from extraction through conversion and use. So far, for example, no one has a completely satisfactory solution to the problem of storing radioactive wastes from fast-breeder reactors. Such problems could result in a significantly slower increase in supply than is needed to meet demand without substantial price increases. On the other hand, if the world learns how to tap fusion, solar energy or geothermal sources on a significant scale, there may be no need to worry

<sup>9</sup> V. E. McKelvey, "Mineral resource estimates and public policy", Seventh McKinstry Memorial Lecture, Harvard University, 23 February 1971.

about global shortages of energy for some centuries to come.

19. Land and water for agriculture are studied in the RFF report, but only for the United States of America, for which supplies of those two resources appear to be relatively abundant in the aggregate, although different parts of the country are likely to experience overcrowding and water shortages which can be overcome only through costly capital projects and migration. The situation is probably the same for the world as a whole: over-all adequacy but severe shortages in individual countries—shortages that can be overcome only through increasing amounts of capital and greater reliance on international trade.

20. While these estimates are conservative in the ways indicated above—in particular because significant technological breakthroughs, discoveries and substitution possibilities were ignored in making the projections—they are over-optimistic in the sense that they ignore the enormous quantities of capital required to exploit these reserves and the growing world-wide imbalances that make such exploitation increasingly risky and difficult in both economic and political terms. Between 1925 and 1967, energy imports into Western Europe, as a fraction of its total consumption, increased from 2 to 61 per cent, and that for Japan, from zero to 80 per cent. Eastern Europe, which exported over 15 per cent of its energy production, currently imports 5 per cent, while the United States shifted from being a 3 per cent net exporter to becoming a 7 per cent net importer. These trends can be expected to continue for at least another decade, increasing the dependency ratio of Western Europe to about 75 per cent, and that for Japan and the United States, to over 90 per cent and 30 per cent, respectively.<sup>10</sup> Corresponding to these figures are dramatically increased exports from a small number of countries, principally in the Caribbean, the Middle East and North Africa. Trends for many other minerals are similar.

21. In response, one can expect major producing countries to attempt to shift terms of trade in their favour, as is already happening in the case of oil, while major consuming countries take increasingly aggressive steps to ensure steady, secure supplies of overseas resources. In this situation, one cannot blithely assume that supplies of new resources will be developed and traded as, when and where needed to keep up with the growth in demand, despite physical adequacy on a global level. The situation for developing countries that do not have such resources to export could become very serious. They may be caught between the growing ability of producing countries to obtain better terms and the ability to pay possessed by developed coun-

<sup>10</sup> Beyond this point, such ratios are difficult to predict because of the efforts that will be initiated to counteract this dependence. One can, for example, expect developed countries to speed up efforts to develop off-shore petroleum sources and nuclear electric production, as well as shale and tar-sands in North America, but difficult environmental problems will have to be faced.

tries, without being able to raise the capital necessary to check their growing dependence upon foreign sources. Clearly, their only long-run solution is to restrict growth in demand, which, in most such countries, must mean population control if levels of living are not to suffer.

22. Thus, while one can say, in general, that physical quantities of natural resources are sufficient to meet demands arising from expected population and economic growth throughout the world during the next 50 years, the development and trading of these resources may not go smoothly, leaving uncomfortably small margins for error, mismanagement, inadequate technological response, trade disruptions and increased consumption resulting from military conflicts. Beyond this 50-year time horizon, the author refuses to speculate. It is clear that such risks and problems will grow as long as natural resource demands grow and that they will recede, at least temporarily, as technological advances and new discoveries relieve the pressure. It is also clear that poor, resource-importing countries will fare worse under adverse conditions than will developed countries and exporting countries; but there is no way of knowing how these diverse trends will develop in different countries or how long this situation can continue.<sup>11</sup>

#### ROLE OF POPULATION AND LEVELS OF LIVING

23. One may question the degree of importance of population growth, as opposed to other factors, such as increased levels of living, in generating these growing demands for natural resources. Once again, the answer depends upon the time horizon involved. If one is concerned with the next five years, monetary and fiscal policy can surely do more to eliminate a shortage of a particular resource than a change in population policy. But the longer the time period, the more important a change in the population growth rate becomes. The answer also depends upon the approach taken, for example, upon what is being held constant in the analysis and upon how the comparison is made. Moreover, the answer will be different for different countries and for different resources.

24. The RFF study referred to above attempted to answer these questions for the United States of America by comparing resource requirements in the year 2000 under alternative assumptions about growth in population and *per capita* gross national product, using a computer simulation-model that permitted the time-

path of all other factors that affect the situation to be held constant between runs. The results indicate that if, by the year 2000, population was to be 1 per cent less than expected, the consumption of resources in that year would be between 0.2 and 0.7 per cent less, depending upon the particular resource considered. A reduction of 1 percentage point in *per capita* GNP in the year 2000 would reduce consumption of resources by from 0.6 to 3.5 per cent. On average, the elasticities for population are about two thirds of those for GNP *per capita*.

25. Before interpreting these results, two additional points should be kept in mind. First, in deriving these results, the change in *per capita* GNP that occurs because of the change in population was permitted to influence the elasticity calculation. A decline in *per capita* GNP can occur independently of a change in population size; but it is difficult to imagine a change in population size that is not accompanied by some change in *per capita* GNP, so long as one assumes no change in the rate of employment and the level of labour productivity. Since a decrease in population tends to be associated with an increase in *per capita* GNP, the effect of the decreased numbers is partially offset by the greater income. As an experiment, the author tried a special run of the model which factored out the population-induced change in *per capita* GNP and found that the elasticities for population in this special case are about the same as those for GNP *per capita*.

26. Secondly, these modelling results do not take into account all the relationships between population, resources and GNP *per capita*. In particular, they cannot reflect the additional risks faced by a country with a lower GNP *per capita*. While a reduction in the growth of *per capita* GNP reduces consumption of resources it also reduces the development of the socio-technical capacity to cope with future resource problems; a reduction in population growth has no such offsetting disadvantages, so far as the economy is concerned.<sup>12</sup>

27. For these reasons, as well as for others detailed in that report, the RFF study concluded that a cessation in population growth in the United States of America was more important as a means of alleviating resource and environmental problems than these numbers indicate. To quote from that study:

"If because of personal preferences, we choose to have more rather than less children per family . . . we

<sup>11</sup> See Donella H. Meadows and others, *The Limits to Growth: A Report for the Club of Rome's Project on the Predicament of Mankind* (New York, Universe Books, 1972). This study, which has recently received considerable publicity, claims that global resource demands cannot continue growing at current rates for more than another 100 years without dramatic increases in world-wide death rates ensuing. While this conclusion follows from the authors' assumptions, there is no adequate justification for making these, rather than some other set of assumptions, for this time period. See the annex to this paper for a brief criticism of this book.

<sup>12</sup> The only possible disadvantage is loss of economies of scale; but for the United States of America and perhaps for all but the smallest countries which enjoy low population-resource densities, this qualification is probably not important. Of greater importance in taking advantages of such economies, if they exist, will be the magnitude of effective demand, which, in addition to sheer numbers, depends upon income levels, internationally as well as domestically, the degree to which tastes are homogeneous, the extent to which income distribution is more equal (and hence tastes more homogeneous), and the degree to which firms are able to take advantage of specialization through horizontal integration, vertical disintegration and international trade.

commit ourselves to a particular package of problems: more rapid depletion of domestic and international resources, greater pressures on the environment . . . and perhaps the continued postponement of the resolution of other social problems, including those resulting from past growth. So long as population growth continues, these problems will grow, slowly but irreversibly forcing changes in our current way of life.

"If we choose to have fewer children per family . . . we purchase time, resources, and additional options: time to overcome our ignorance and to redress the mistakes of past growth, resources to implement solutions, and additional freedom of choice in deciding how we want to live in the future.

"Similar consequences could emerge from the choice open to us with respect to alternative rates of economic growth. . . . But growth in the economy can be utilized for different ends than it is put to now. While it adds to problems that need solution, it also adds to capacity to solve problems. It is difficult to find similar offsetting advantages from additional population growth at this stage in United States history".<sup>13</sup>

28. If similar studies were available for other countries, they would undoubtedly suggest a larger role for variations in population growth, especially in developing countries. First, all the elasticities for both population and GNP *per capita* are probably larger. Except for land for agricultural purposes, the material intensity of GNP tends to be low for very poor developing countries but rises very quickly as GNP *per capita* increases; national intensity then begins to fall off again as high levels of income are achieved. The United States and other older developed countries are in a declining phase, while most other countries are still rising.

29. Secondly with lower incomes *per capita*, and often with higher population resource densities, the elasticities associated with population are likely to be greater relative to those for GNP *per capita*.

30. Of primary importance, however, as was suggested in the previous section is the fact that developing countries are far more vulnerable than developed countries to resource shortages. Their only long-run hope to reduce this vulnerability, a vulnerability that is likely to grow with time, is a reduction in population growth so that a larger fraction of output can be devoted to improving the capital stock and the quality of human inputs into the production process.

31. The implications for population policy should be fairly clear. So far as resources are concerned, there seems to be nothing to gain and much to lose from continued population growth. The importance of this conclusion varies by country, being greatest in developing countries lacking a good natural-resource base and in countries with high rates of population growth. Almost all countries, however, stand to gain something from a reduction in population growth rates.

32. The implications for policies pertaining to economic growth are less clear. No one would suggest that developing countries should limit growth in their *per capita* incomes as a means of conserving resources. Indeed, perhaps the most important benefit from a reduction in population growth is that the savings it permits may be used to induce a more rapid growth in *per capita* incomes. But the question must be asked whether there is any justification for already developed countries further increasing their consumption of the world's scarce resources.

33. If one could be reasonably confident that developing countries would benefit from a decrease in consumption of natural resources on the part of developed countries, and if the rate of technological advance were not adversely affected in the process, it is difficult, considering the problems of the world as a whole, to find any justification for developed countries increasing their consumption of the world's scarce resources. However, a reduction in the consumption of resources by developed countries would not automatically help developing countries. This reduction would be of help only if the sale of these raw materials by developing countries were not an important fraction of their export earnings (but for many it is) and if some means could be found to transfer to them in usable form the resources that the developed countries release by consuming less. Permitting these resources to remain idle does not help the developing countries. Nor will permitting such resources to remain idle help future generations, if in the process a poorer socio-technical and capital base is passed on to them. The grandchildren of this generation of mankind will not be grateful for the conservation of fossil fuels if, as a consequence, the mysteries of fusion are not solved.

34. What is called for, therefore, is not so much a reduction in economic growth-rates by the developed countries as a reordering of priorities, priorities that stress increased assistance to developing countries and increased emphasis on the kinds of scientific and technological development that will result in the creation of new resources for the future.

## ANNEX

### A Note on *The Limits to Growth*<sup>a</sup>

*The Limits to Growth* purports to demonstrate that the only way to avoid cataclysmic increases in world-wide death rates within the next 100 years is to stop all population and material economic growth throughout the world during the next two decades or so. But this demonstration is not convincing on at least three counts.

First, the model used contains few of the important adjustment mechanisms that have helped the world avoid similar catastrophes to date. There is no price mechanism to signal pending shortages, to make it profitable to invest more in exploration and research or to induce consumers to reduce their consumption and shift to substitutes. There is no Government to monitor the situation and to supplement the price mechanism where it does not provide adequate signals. Nor does anyone learn from the experience of others and change his behaviour accordingly. In its review of the book, the Task Force of the International Bank for Reconstruction and Development (World Bank) states:

"Can we really believe that most of the population of Detroit could succumb to persistent pollutants without the rest of humanity making any adjustments in its producer-consumer behavior? Humanity faces these problems one by one, every year in every era, and keeps making its quiet adjustments. It does not keep accumulating them indefinitely till they make catastrophe inevitable. One does not have to believe in the invisible hand to subscribe to such a view of society. One has merely to believe in human sanity and its instinct for self-preservation."

Closely related are the problems arising because of the extreme degree of aggregation incorporated in the model. There is only one composite industrial output, one non-renewable resource, one "pollutant" and one geographical unit, the world as a whole. Not only does such a formulation greatly reduce the confidence one can have in the postulated relationships between the aggregates, it greatly compounds the problems arising from inadequate adjustment mechanisms. Consumers cannot substitute between outputs, producers cannot substitute between resources, society cannot alter the composition of output, e.g., deciding to spend less on military equipment and more on research, development and exploration. Since the model does not allow for these possibilities, there is really no alternative to reductions in population and economic growth.

Thirdly, the study incorporates highly pessimistic assumptions about technological progress, future reserves of non-renewable resources, the ability to control and absorb pollution and the extent of population growth that is likely in the next two centuries. In addition to leaving out the possibilities of

such technological breakthroughs as fusion and solar energy—the omission of which may make sense in a 50-year time horizon, but not when projecting beyond that—the use of shale oil, tar sands and geothermal sources of energy were ignored. The authors allow for the possibility that reserves of their aggregate resource could increase five times over the next 100 years, a seemingly generous allowance until it is recalled that, according to the U.S. Bureau of Mines, reserve estimates of iron ore increased about five times between 1954 and 1965 and that for copper by 3.5 times since 1935. Moreover, promising underwater sources of minerals are ignored: in reviewing this possibility, IBRD finds that within the next 20 years it should be possible to recover on a commercial basis 100 million tons of nodular materials from the sea-bed each year, and that such recovery could be increased and sustained "indefinitely" at a level of 400 million tons. The smaller of these figures "would add to the annual production of copper, nickel, manganese and cobalt to the extent of roughly one fourth, 2 times, 6 times, and 12 times respectively, compared to the current free-world production levels". One need not concur in detail with this judgement in order to assert that this possibility should not be ignored.

As concerns pollution, there is no scientific evidence for the functional relationships assumed in the model: for the amount of pollution that can be safely absorbed by the earth's environments; for the effect of pollution on birth and death rates; or for the degree to which treatment and changes in process can reduce pollutant emissions per unit of output. And with respect to population growth, the historical relationships between birth and death rates and the level of development cannot blithely be projected into the long-term future; public health and family planning programmes, the availability of modern contraceptives and spread of knowledge about them and changing attitudes towards marriage and sex are all operating to weaken the historic linkages. Indeed, recent census materials (not available at the time *The Limits to Growth* was written) suggest that a slow-down in population growth may have already begun in 56 out of 66 countries for which data are available.

Contrary to what the book says, all these factors can make a significant difference in one's estimate of when and how growth must stop. First, a correction of the overly pessimistic assumptions could result in a postponement by several centuries of the date at which growth must stop without introducing additional adjustment mechanisms. Secondly, as that limit is approached, all kinds of adjustment mechanisms will come into play to slow and elongate the decline. Indeed, the idea of talking about a specific "date" is erroneous. The adjustments are continuous and occur without benefit of any social knowledge that some limit is being approached. Assuming that nuclear war is avoided, the end of the world will surely come "not with a bang but a whimper".

## ENERGY RESOURCES \*

Amory B. Lovins \*\*

### BACKGROUND INFORMATION

#### *Scope and purpose*

1. As medical science, by deferring death, has allowed many more people to live on the earth, so the energy of fossil fuels, by deferring physical scarcity, has kept those people alive. Medical technology has caused a population explosion; energy technology, at least for some, a wealth explosion. How many people can continue to live on the earth for how long and with what wealth depends upon the ingenuity and wisdom with which man uses energy. Yet, on a planet that is round and therefore finite, energy conversion must eventually encounter some geophysical outer limit; and even sooner, it may be constrained by lack of resources, by biological side-effects, by technical problems, or by social, political and economic pressures.

2. Exploring these constraints and the ways in which they interact with the numbers and goals of people in widely differing societies is arguably the most complex problem in the world today, and one of the most important. Energy problems are inseparable from problems in almost every area of economic, foreign, industrial, agricultural and social policy. Any brief survey of world energy strategies must therefore be exploratory rather than definitive, synthetic rather than exhaustive. Furthermore, so many energy problems are controversial, unsolved or perhaps insoluble, that there are few easy or canonically received answers. This summary of a tangled and fast-moving field cannot present a consensus where none exists, but can only suggest where the merits of a dispute may lie and undertake to represent a respectable body of technical opinion. The objective of this paper is to outline certain assessments and conclusions on which much top-level energy thinking has in recent months begun to converge, presenting such information, and no more, as is needed to convey a sound grasp of the subject.<sup>1</sup>

#### *Sources*

3. This paper does not obscure the basic outlines of energy problems with a flood of charts, tables and

\* The original text of this paper (E/CONF.60/SYM.III/12/Rev.1) was submitted to the Symposium on Population, Resources and Environment, Stockholm, 26 September-5 October 1973.

\*\* Former Fellow at Oxford University.

<sup>1</sup> No expert can tell the whole story, nor avoid emotional entanglement with particular ideas.

graphs—in part because words tell most when spiced, not smothered, with data, and in part because so many energy data prove on close acquaintance to be inconsistent, unreliable or irrelevant. A high official of the Atomic Energy Commission of the United States of America, discussing nuclear power costs, once summarized memorably (if inadvertently) the status of most energy statistics. He remarked:

“Figures in the literature . . . vary by at least a factor of ten. I am not going to try . . . to give you more accurate . . . figures for three very good reasons:

“(1) They do not exist even within the Atomic Energy Commission;

“(2) If they did exist they could not be released for security reasons;

“(3) If they did exist and if they could be released I wouldn't believe them anyway.”

Likewise, since a thorough bibliography would be far longer than this paper, highly selective references are cited only for specialized statements that might seem especially obscure or controversial, not for those based on standard sources.

4. The present paper draws relatively little on the dozens of energy studies now under way in many countries, for these studies are usually of short-term national fuel policy,<sup>2</sup> not of long-term world energy policy, and tend to neglect such fundamental issues as the role of energy in society. This paper does not go so far as to suggest (as some do) that fuel shortages should be relieved by burning energy studies; but the implications of man's energy conversions must be examined from a far wider perspective than that of the technologist, economist or other specialist alone. This has been done so infrequently that no country on earth appears to have either a coherent long-range energy strategy or the institutions needed to devise one.

#### *Time-scale*

5. Since this paper is concerned with strategies far more than with tactics, it takes into consideration what must be done now and in future to produce a sustainable energy economy from the mid-1980s onwards, not what *ad hoc* programmes might extricate the world

<sup>2</sup> Obvious discrepancies emerge if national studies are combined: Japan, for example, was for several years planning to import more petrol than anyone seems to have been planning to produce.

from its current acute difficulties. These two time-scales, "strategic" and "emergency", must be carefully distinguished. The major problems today are *ipso facto* insoluble, for it takes time to solve problems, and all there is time for now is temporary expedients; but the problems of the mid-1980s and beyond might be soluble if attacked now. This paper therefore focuses directly on how to solve the problems that the world will face after immediate uncertainties have been resolved, and only indirectly on how to muddle through meanwhile. This approach is, perhaps, brutal and in no way intends to underestimate the risks to be faced over the next decade or so (e.g., the risk of further military adventures in the Middle East); but it is a necessary approach if one is to break the cycle of poor planning that has put mankind into this position. Energy strategy must, in a sense, work backwards: one must ask what cannot be done now if one is to retain the options that will be needed later. This approach leads one to conclude that most energy decisions today are based on unsound assumptions and are heading in an unsustainable direction. Those assumptions, therefore, are contrasted with other that could prove more useful.

#### Emphasis

6. Energy studies are traditionally built around a survey of physical inventories of fuel resources and often place less stress on constraints of production. This paper uses the opposite emphasis. A resource inventory would, by itself, be useless in understanding world energy problems, for energy constraints are not mainly dictated by physical scarcity, but are instead geopolitical, environmental and socio-technical rate and magnitude problems. Current technology makes it physically possible to convert enough energy to make the earth rather moon-like; this fact is impressive but irrelevant, since what matters is how fast and with what political and environmental side-effects human energy needs can be met. The nature of these constraints forms the focus of this paper. It also demands four departures from commonly heard economic arguments.

7. First, discussing fuel availability in purely economic, rather than in partially physical, terms—discussing reserves to the exclusion of resources, or prices to the exclusion of actual production—is not correct. Fuel minerals, unlike other minerals, are not merely dispersed, but are physically consumed by combustion: the cost of natural gas is notional once the last molecule of gas has been burned, and before that happens, the price may reflect more the exigencies of current exploitation than the long-term scarcity-value of the residual stock. Likewise, the landed price of Libyan crude is irrelevant if the Libyan Arab Republic refuses to ship any: major consumers are now discovering belatedly that it is sudden real scarcity, not rising price, that requires them to use less oil. Both these divergences of theory from reality show that money and goods are not always equivalent. Though the price mechanism rightly places a high premium on, for

example, all rare minerals, it also places an exceedingly high premium on live dodos.

8. Secondly, the price of energy is, in a sense, less important to the energy planner than to the consumer. Energy prices have little to do with energy costs—especially with external (or, as Garrett Hardin calls them, "larcenous") costs—but are, instead, fixed mainly by Governments and corporations after their energy policies have been decided upon grounds other than future price. Thus, including largely fictitious energy prices in economic models of energy flows can lead to circularity.

9. Thirdly, economists tend to divide energy flows into such "black-box" categories as "supply" and "demand" or "energy sources" and "energy uses". This obscures the physical process, namely, long, continuous chains of energy conversions proceeding from various forms of high-grade energy to low-temperature heat, as required by the second law of thermodynamics. Substituting economic abstractions for thermodynamic realities leads, for example, to burning natural gas to raise steam to generate electricity to heat a house, boil water or dry clothes—which could all be done directly by the gas from three to six times as efficiently.<sup>3</sup>

10. Lastly, almost every economic analysis forgets that man's energy flows are not mere ciphers on a page, but part of a larger and far more complex network of natural energy flows that are often of similar magnitude. Every change man makes in natural energy flows is a biological and social act. Accordingly, this paper is about how the world works, not about the way one might wish it worked; about the functioning biological world, not an imaginary inanimate one. This approach may help us to learn from the observed working principles of a world that for 3 thousand million years has been patiently designing stable energy-consuming systems in accordance with physical law.

#### Units

11. Units of measure based on the *Système internationale* are used in this paper. These units are the metre (m), kilogramme (kg) and second (s). In this system, the unit of power is the watt (W). For example, one's body dissipates 100 W of heat. The unit of energy is the joule (J), equal to a power of 1 watt applied for 1 second. Conversely, a watt is a joule per second ( $1 \text{ W} = 1 \text{ J/s}$ ). One thousand joules (1 kJ) is equal to  $10^{10}$  ergs, or to 0.239 kilocalorie (kcal), or to 0.948 British thermal unit (BTU), or to  $2.78 \times 10^{-4}$  kilowatt-hour (thermal) (kWh(t)), or to approximately  $3.4 \times 10^{-5}$  kg of coal equivalent. Conversely, 1 metric ton (1,000 kg) of coal, or about 0.7 metric ton of oil, is equivalent to about 8.1 MWh(t)<sup>4</sup> or about  $2.9 \times 10^{10}$  J.

<sup>3</sup> United States of America. Ninety-second Congress, Senate, Committee on Interior and Insular Affairs, *Conservation of Energy*, prepared by H. Perry (Washington, D.C., Government Printing Office, 1972).

<sup>4</sup> One MW =  $10^6$  W = 1,000 kW = 1,000,000 W.

12. The foregoing remarks make it possible to survey very briefly the current world energy position. Estimates of the current rate of man's global energy conversion disagree by  $\pm 25$  per cent, but most people would agree on  $8 \times 10^{12}$  W as a round number. This is nearly 20 times the energy of a standard diet for the world's population as computed by the Food and Agriculture Organization of the United Nations (FAO). Thus, global industry already uses about 20 times as much energy as is recovered from all agriculture and hunting on both land and sea, and gives everyone the equivalent of about 12 hard-working slaves.<sup>5</sup> In density of energy per unit of continental area, human energy conversion is now about two fifths as great as net photosynthesis and is roughly equal to the natural outward flux of geothermal heat from the interior of the earth.<sup>6</sup>

13. On a world average, human energy conversion is increasing almost three times as fast as population, i.e. at about 5.7 per cent per annum, equivalent to an increase of 4.5 times by the year 2000. Annual growth is typically<sup>7</sup> 1-3 percentage points more rapid in poor countries than in, say, the United States of America (just over 4 per cent per annum)—which, however, with less than 6 per cent of world population, uses over one third of world energy, or roughly twice the combined total for Africa, the remainder of North and South America, and all of Asia, excluding Japan. This staggering inequality of energy distribution is among the most striking and disquieting features of the current energy picture. Gaps of one or even two orders of magnitude (= factors of 10) are common: e.g., *per capita* energy consumption is 250 times greater in the United States compared with Nigeria. (Likewise, some 94 per cent of human energy conversion is in the northern hemisphere, and 75 per cent is in perhaps 0.3 per cent of the land area of the earth.)<sup>8</sup> Yet, whatever correlation may exist between *per capita* energy conversion and various social indicators is controversial, tenuous and non-linear. Few Americans, for example, would argue that they live twice as well as the British or three times as well as the French, in proportion to their *per capita* energy conversion. Even correlations of *per capita* gross national product (GNP) (hardly a reliable social indicator) with *per capita* energy conversion show very large scatter from country to country.

<sup>5</sup> Each slave is assumed to require 175 W or about 3,600 kg-cal/day—equivalent to about 0.5 kg coal per day.

<sup>6</sup> *Inadvertent Climate Modification: Report of the Study of Man's Impact on Climate (SMIC)* (Cambridge, Mass., and London, Massachusetts Institute of Technology Press, 1971).

<sup>7</sup> There are many exceptions, principally in countries with severe population pressures: e.g., energy conversion *per capita* is growing about one fourth as fast in India as in the United States of America and one fifth as fast in the European Economic Community.

<sup>8</sup> *Inadvertent Climate Modification, loc. cit.*

14. Growth in energy conversion in the rich countries is the product of growth in population, in material consumption *per capita* and in the use of energy-intensive technologies. The first two, and probably the third, are growing exponentially in most countries. The relative weight of these three factors is speculative, though in many rich countries population growth appears to be less important than the other two combined. (However, the unit environmental impact of population growth is, of course, far greater than in areas with low energy *per capita*.)

15. In some of the countries with the highest gross national product, energy conversion per unit of GNP is probably increasing, owing to changes in technologies (e.g., from natural to synthetic materials), and to such market shifts as electrification—heavily encouraged through advertising, promotional rates and other tactics by an energy industry that tends to identify the national interest with its own. (In the United Kingdom of Great Britain and Northern Ireland, one branch of the nationalized electricity industry will cheerfully sell an electric fire for £7, which commits another branch to installing more than £200 worth of capacity—but which successfully competes with similar promotional efforts by the nationalized gas industry.) Energy promotion has led to widespread confusion between demand and need. It also supports self-fulfilling prophecy, whereby energy planners first predict a doubling of, say, electrical production in 10 years and then work hard to make it come true—and complain about how difficult it is.<sup>9</sup> The world-wide rush to acute epidemic “energitis” reminds many thoughtful observers of Santayana's remark: “Fanaticism consists in redoubling your efforts when you have forgotten your aim”. Energy conversion seems to have become a social good to be maximized.

16. The profligacy of industrial societies is founded on a pervasive attitude: that energy is a virtually free good that can be substituted for all other forms of capital. (Some examples are studied below.) In most of the world, however, necessity enforces a very different attitude: that energy is an expensive good which one can scarcely afford to substitute for anything, and which one will be even less able to afford as the extravagance of others exhausts cheap reserves and drives up the price. Countries with expanding industry, rapid population growth (often with skewed age structure) and a trend towards intensive agriculture will be hit especially hard by economic energy scarcities beginning very soon. It is these countries that rising energy prices will most damage—not the industrial countries, for which far more expensive energy is long overdue.

#### Supply pattern

17. Although no commercial source of high-grade energy can be considered in isolation, the basic global

<sup>9</sup> Surprisingly, many energy promoters simultaneously proclaim “Energy crisis” and “Use more”.

statistics of major sources<sup>10</sup> are easily summarized in approximate and aggregated form:

(a) About 97 per cent of primary energy comes from fossil fuels, which are non-renewable except in geological time. This overwhelming commitment comprises:

- (i) Approximately 38 per cent solid fuels (consumption rising relatively slowly and with fluctuations);
- (ii) Approximately 40 per cent oil (consumption doubling about every decade);
- (iii) Approximately 19 per cent natural gas (consumption doubling about every 7-8 years);

(b) Hydroelectricity provides only about 2 per cent of world primary energy, and geothermal energy far less;

(c) Nuclear fission, wood and other sources probably account for less than 1 per cent each;

(d) This global pattern masks wide regional and national variations: the United States of America uses nearly two thirds of world gas; Japan uses almost twice as much oil as coal, but almost no gas; the Union of Soviet Socialist Republics relies heavily on coal; many of the less industrialized countries have disproportionate hydroelectric production, and some burn substantial amounts of vegetation or animal wastes<sup>11</sup> for fuel.

#### *Demand prospects*

18: Before one critically assesses the outlook for these and other sources of primary energy, it is important to observe that many proposed technologies would make the rate of increase of world energy conversion rise even more rapidly than it currently appears to be doing. For example, modern (as opposed to traditional) agriculture already requires fossil-fuel subsidies so heavy that, according to one estimate,<sup>12</sup> it is often necessary to supply several times as much chemical and mechanical energy as is recovered in food—about five times as much in all food production in the United States, compared with perhaps one fiftieth in Chinese wet-rice farming. But this is only the beginning, as is shown below:

(a) For world food yields to keep pace with the population growth which will occur, if mortality rates do not greatly increase (due to the failure of food supply to keep pace), production of nitrate fertilizer must increase approximately 100 times in this century. (This is consistent both with projections of recent demand

<sup>10</sup> What is meant here, of course, is industrial energy, and one must not forget that in many countries, the main source of energy is people. People are extremely efficient users of food (if they get enough), and the food itself takes little energy to grow (see below), if energy-intensive agriculture has not yet taken over from traditional methods.

<sup>11</sup> India is said to burn  $1-3 \times 10^{11}$  kg/yr of dung: compare this to coal consumption in the United Kingdom of  $1 \times 10^{11}$  kg/yr.

<sup>12</sup> M. J. Perelman, "Farming with petroleum", *Environment*, vol. 14, No. 8 (October 1972), pp. 8-13.

and with observed diminishing returns in nitrogen take-up.) Current technology—recently much improved, and probably hard to improve much further—demands about 2 kg of coal equivalent as direct energy input per kilogramme of fixed nitrogen.<sup>13</sup> (A breakthrough in microbiological nitrogen fixation may or may not reduce this cost.) Such energy costs imply that nitrogen-fertilizer factories alone, in the year 2000, may require about 20 per cent of current total world energy use to produce  $\sim 8 \times 10^{11}$  kg nitrogen per annum.

(b) Desalinating sea water requires 3 kJ/litre in theory<sup>14</sup> about 170 in current practice and (speculatively) about 50 in very large-scale future practice.<sup>15</sup> The energy requirements of extensive desalination are thus impressive. For example, under reasonable assumptions,<sup>16</sup> desalinating enough sea water to grow one average man's subsistence crops could well require as much energy as he now uses for everything. This is to say nothing of capital, rate and magnitude, or environmental problems.

Metals further illustrate the energy-intensiveness of cornucopian technologies:

(c) Producing 1 kg of aluminium from alumina requires 16 MJ ( $= 1.6 \times 10^7$  J) in theory, and about three or four times as much in practice—perhaps a few kWh of primary energy per beer-can. (The doubling time of world aluminium production—currently about  $10^{10}$  kg/yr—is less than a decade.) It is less commonly realized that metals with lower binding energies but higher entropy can be nearly as energy-intensive: just mining and beneficiating ore yielding 1 kg of copper, for example, takes about 50 MJ.<sup>17</sup> Total direct energy inputs<sup>18</sup> for producing certain metals are:

- (i) Copper from 1.0 per cent sulphide ore in place (1940s)  $\sim 54$  MJ/kg;
- (ii) Copper from 0.3 per cent sulphide ore in place (1980s)  $\sim 98$  MJ/kg;
- (iii) Aluminium from 50 per cent bauxite in place (1970s)  $\sim 204$  MJ/kg;

<sup>13</sup> G. Leach, personal communication, 1973.

<sup>14</sup> This calculation of the thermodynamic minimum energy is based on the osmotic pressure of salt, derived from the ideal gas law. It assumes infinitely slow, reversible desalination—hence the gap between theory and practice.

<sup>15</sup> A. M. Weinberg and R. P. Hammond, "Limits to the use of energy", *American Scientist*, vol. 58 (1970), pp. 412-418; A. M. Weinberg, "Nuclear energy and the environment", *Bulletin of the Atomic Scientists*, vol. 26, No. 6 (June 1970), pp. 69-74.

<sup>16</sup> It is assumed here that a mean-flow of 1 m<sup>3</sup>/day, desalinated by 100 MJ/m<sup>3</sup> and pumped by 20 MJ/m<sup>3</sup>, will grow (after evaporation losses) 2,500 net recoverable kg-cal/day of protein-rich crops. These crops are assumed to form 90 per cent of the diet, and the remainder is assumed to be derived from the crops at 5:1 conversion.

<sup>17</sup> Organisation for Economic Co-operation and Development, *Gaps in Technology: Non-ferrous Metals* (Paris, 1969); A. B. Lovins, *Openpit Mining* (London, Earth Island, 1973).

<sup>18</sup> J. C. Bravard, H. B. Flora II and C. Portal, "Energy expenditures associated with the production and recycle of metals", ORNL-NSF-EP-24, Oak Ridge National Laboratory, November 1972. Transport costs for both products and raw materials are neglected; the assumed conversion efficiency of primary fuel to electricity is 40 per cent.

- (iv) Magnesium from sea water (anytime)  
~ 360 MJ/kg;
  - (v) Titanium from ilmenite in place (1970s)  
~ 593 MJ/kg;
- Compare combustion of coal, which yields  
~ 29 MJ/kg;

(d) Energy costs for leaner sources will be higher: in particular, comminution (crushing and grinding) of typical non-ferrous ores to liberation size now requires about 50-80 kJ/kg ore;<sup>19</sup> implying total production energies of the order of  $10^{10}$  J/kg metal in a  $10^{-5}$  "ore". This enormous energy cost is important because it appears likely that for most non-structural metals there is not a continuum of progressively poorer ores to be mined at steadily increasing cost in energy and land, but, rather, an abrupt grade gap, often of  $10^3-10^4 \times$ <sup>21</sup>, between mineralized and barren rock. Thus, for some such metals, mining energy may rise by orders of magnitude several decades hence.

One of the few bright spots in this outlook is that, contrary to what energy promoters often suggest, technologies for abating pollution and for recycling scarce materials are rarely energy-intensive, and often yield net energy savings.<sup>20</sup>

19. In summary, the current trend towards substituting energy for other resources—rich ores, fresh water, highly productive ecosystems etc.—suggests that if energy supply were not constrained in any way, demand would rise very steeply. In such circumstances, one can easily envisage, by late in this century, a doubling of current growth rates. However, this is not going to happen, and indeed the current energy growth rate cannot be maintained for long.<sup>21</sup> To explain why this is so, one must examine the outlook both for fossil-fuel supply and for those new energy sources which prophets of the "Second Coming of Prometheus" believe will prevent scarcity. Following this, alternative strategies and the issues they raise, including climatic constraints, are discussed.

#### *Possible rates of innovation*

20. To place in perspective the supply problems of fossil fuels, one must stress a basic insight more common among engineers than among politicians: the truly formidable rate and magnitude problems of any major innovation. The aggregate amounts of energy now being converted are so prodigious that voluntary rapid change in supply patterns is physically impossible. For example, suppose that the present world conversion rate of  $8 \times 10^{12}$  W continues to grow (as most authorities predict and urge) by about 5 per cent per annum for

<sup>19</sup> A. B. Lovins, *op. cit.*

<sup>20</sup> T. S. Lovering, "Mineral resources from the land", in National Academy of Sciences, *Resources and Man* (San Francisco, Calif., W. H. Freeman, 1969); H. Perry, *op. cit.*

<sup>21</sup> The argument, implicit in much of this paper, that all energy forecasts are probably wrong, may seem a well-aimed boomerang if followed by an energy forecast. It is easier, however, to forecast correctly by an energy forecast. It is easier, however, to forecast correctly what will not happen than what will happen.

the rest of this century, an increase of 3.7 times to about  $3 \times 10^{13}$  W. If one could in some way build one huge (1 GW = 1,000 MW (e) =  $10^9$  W (e)) nuclear power station per day for the rest of this century, beginning today, when one had finished, more than half of the world's primary energy would still come from fossil fuels, which would be consumed about twice as fast as now. This is an optimistic case, in that it is hard to think of any knowledgeable person who considers such a rapid nuclear infusion possible, even were it advisable. On the other hand, such rapid sustained growth in energy conversion as has just been assumed will not actually occur, owing both to supply constraints and to the moderation in demand which these constraints will encourage and compel.

#### OIL

21. The pattern of constraints emerges most clearly for oil, the main source of fossil energy capital (10<sup>8</sup>-year-old sunlight) currently being consumed—and a source whose total effective lifetime will probably be 70-80 years.<sup>22</sup> The most important single datum here is that roughly two thirds of the ultimately recoverable oil resources of the world, and a similar fraction of current reserves, are found in the unique Persian Gulf region. (Most of the remainder is divided among the USSR, the western hemisphere and, to a lesser extent, Africa.)

#### *Exploration*

22. Geological knowledge no longer justifies the hope that new discoveries, though they will be extensive and sometimes tactically important, will significantly alter this strategic picture. The conditions necessary for the occurrence of oil, and the location of the earth's main sedimentary basins, are now sufficiently well known for total recoverable resources to be estimated with some confidence.<sup>23</sup> The substantial deposits which remain to be proved will not greatly shift the time of ultimate physical depletion (namely, in the first third of the next century, assuming that consumption continues to grow rapidly for the next 15-20 years, as projected by virtually all Governments): if oil consumption continues to double every decade, then a doubling of world reserves will delay depletion by only a decade.

23. Indeed, to maintain a healthy ratio of reserves to production, one should find each year several new deposits, each comparable to the North Sea, or even to the Alaskan North Slope. This is not happening, and there appears to be no likelihood whatever that technical progress will make it happen, for undiscovered oil is now scarce. Since the easier areas outside the well-known producing provinces have already been explored, most new exploration is now in remote, hostile and fragile environments (such as the Arctic and the outer

<sup>22</sup> M. K. Hubbert, "Energy resources", in National Academy of Sciences, *Resources and Man* (San Francisco, California, W. H. Freeman, 1969).

<sup>23</sup> *Ibid.*

continental shelf). Despite great effort and ingenuity, discovery rates in the United States<sup>24</sup> have fallen steadily from over 800 barrels<sup>25</sup> per metre drilled in the 1930s to perhaps 100 today,<sup>26</sup> and similarly abroad. Accordingly, prominent exploration experts have recently predicted that total world oil production will peak about the beginning of the 1980s and decline thereafter.

24. A few data about the widely acclaimed North Sea basin may help to put new discoveries into perspective. The entire North Sea reserves, once proved, are expected to amount to some 1.5-1.8 per cent of ultimately recoverable world resources. North Sea oil is costly to discover (about £ 2 million per 4,000-m wildcat hole) and to extract (about £ 40 million to build a single platform producing 10<sup>5</sup> barrels per day, plus about £ 15,000 per day to run it). It will cost, from £ 6 thousand million to £ 10 thousand million to produce the likely total capacity of the North Sea, perhaps from 6 million to 8 million barrels per day (3-4 × 10<sup>8</sup> tons per annum) in the mid-1980s; yet this is not enough oil to cover the projected increase in oil consumption in Western Europe (currently about 15 million barrels

<sup>24</sup> These figures are somewhat distorted by institutional forces, including peculiar United States tax laws which can encourage unsuccessful drilling. None the less, the world ratio of reserves to production has been falling for some years and shows no sign of recovery.

<sup>25</sup> Approximately 7 barrels (the customary unit) of crude oil weigh 1 metric ton. One barrel is thus approximately 5.8 GJ = 5.8 × 10<sup>9</sup> J.

<sup>26</sup> M. K. Hubbert, *loc. cit.*

per day and doubling recently every 8-10 years.<sup>27</sup> The required off-shore technologies, too, meet or exceed the safe limits of those now available,<sup>28</sup> giving rise to unknown but possibly great environmental risks, and the likelihood that the social disruption<sup>29</sup> of sudden industrialization will be increased by an unfavourable trade-off between the oil and fishing industries.<sup>30</sup>

### Costs

25. A short table, concentrating on broad ranges rather than on technical details, summarizes more generally the approximate costs of producing crude oil or its energy equivalent from various areas or methods—both the capital cost of 1 barrel per day and the technical unit cost of a barrel at the well-head (including exploration and lifting costs, but excluding carriage, taxes, producing Government's economic rent and producing firm's profit):

<sup>27</sup> It is not obvious, however, that the oil will stay in Europe: trans-shipment to the United States of America is a likely result of United States-Japanese competition for low-sulphur crudes. In the spring of 1973, an American oil executive made headlines at Oslo by advising Norwegians to sell their oil immediately, before it was rendered worthless by new energy sources being developed across the Atlantic: what he meant was, "I want your oil now."

<sup>28</sup> N. Sanders, "North Sea oil: can technology cope?", *New Scientist*, vol. 56 (16 November 1972), pp. 380-382.

<sup>29</sup> J. Francis and N. Swan, *Scotland in Turmoil* (Edinburgh, Church of Scotland Home Board, 1973).

<sup>30</sup> Many would argue that the social cost of hasty oil development can be even higher; in Alaska, for example, the extinction of a native culture.

Energy source	Capital cost (Pounds/barrels/day)	Technical unit cost (Pounds/barrel)
Persian Gulf	40 — 120	0.04 — 0.08
Nigeria	250 — 330	0.16 — 0.25
Venezuela (excluding heavy oils), Far East, Australia	280 — 400	0.16 — 0.25
North Sea, most other Europe	1,000 — 1,600	0.36 — 0.80
Large deep-sea reservoirs	over 1,200?	0.80 — ?
New reservoirs in United States of America (not too remote)	1,200 — 1,600	0.80 — 1.00
Easy part of Alberta tar-sands	1,200 — 2,000	0.80 — 1.20
High-grade oil-shales	1,200 — 2,800	1.20 — 1.90
Gas synthesized from coal	2,400 — 3,200	1.20 — 2.40
Liquid synthesized from coal	2,400 — 3,200	1.20 — 2.40
Liquefied natural gas (landed)	2,400 — 5,000	1.20 — 2.40
Nuclear fission (light-water reactor)	3,500 — 5,500	?

This table makes clear the enormous leverage exerted by holders of large reserves at low technical unit cost. It is this virtual monopoly, not on energy, but on cheap energy, that is rapidly bringing the era of cheap energy to an end:<sup>31</sup> from now on it is a matter of what the

<sup>31</sup> This has somehow come as a surprise to many: even in February 1970, the United States Cabinet Task Force on Oil Import Control could report that "we do not predict a substantial price rise in world oil markets over the coming decade". (The price was then \$2 per barrel.) In the United Kingdom, documents released by the Central Electricity Generating Board in the spring of 1973 revealed the assump-

tion that fuel costs would rise a few tens of percentage points to 1980 and remain constant thereafter. A. B. Lovins, "Things that go pump in the night", *New Scientist*, vol. 58 (31 May 1973), pp. 564-566.

Iran, may well follow suit in the next few years (regardless of the outcome of current negotiations).

### Foreign policy

26. Into this volatile market, the United States of America is suddenly emerging as a major oil importer in direct competition with other buyers, both rich and poor—most notably with Japan and the European Economic Community (EEC), both already absolutely dependent upon Middle Eastern oil. With its own oil and gas resources heading for virtual exhaustion by about the turn of the century<sup>32</sup> the United States has long planned to import about 10 million barrels per day in 1980 and twice that much (one fourth of its total energy consumption) in the mid-1980s, implying a gross annual dollar flow to the Middle East rising from about \$8 thousand million currently to from \$20 thousand million to \$40 thousand million<sup>33</sup> or possibly a good deal more. If the balance of payments of the United States and the productive capacities of the Middle East (both technical and political) could support such a drain, which seems implausible, the immense dollar liquidity of the producing countries would then permit disruptive short-term capital flows, price wars, heavy spending on armaments<sup>34</sup> and extensive downstream investment. Such energy dependence can also be politically exploited.<sup>35</sup> Strategic stockpiling of oil to reduce political risks is awkward and costly (about as much as the landed price of the oil); it is also unlikely to be sufficient for a prolonged interruption, the current Western European stock of from two to three months being perhaps a typical maximum lifetime.

27. The risk run by firms investing in such capital-intensive areas as the North Sea, while other areas contain tens of times as much oil at a tenth the technical unit cost, will likewise be substantial—especially because only large fields (similar to those that now contain nearly three fourths of current reserves) can support the high cost of exploration and production in such areas. None the less, countries that believe they can retain access to off-shore reserves are, without ex-

ception, planning massive investment and immediate rapid extraction; for example, North Sea oil production in the Norwegian sector is to peak in 1977, decline to half its maximum within about four more years and decline further to almost zero by 1990.<sup>36</sup> (Gas production is to peak by 1980-1987.) The cogent arguments<sup>37</sup> for delayed and stretched production appear to carry no weight with Governments whose resource decisions are apparently made by accountants on the basis of discounted cash flows.

### Recovery

28. Only about 30-35 per cent of the oil in place in an average reservoir is currently recovered (compared with about 80 per cent for gas, 55 per cent for underground-mined coal and 80 per cent for surface-mined coal).<sup>38</sup> As prices double or treble, intensified secondary and tertiary recovery may be expected to increase oil recovery by 5-10 per cent; recovery rates have risen by about 10 points in the past two decades. In some cases (e.g., Venezuelan heavy oils) improvements may be greater. Recoveries of the order of 50-60 per cent are not expected to become common, however, if only because the amount of energy going down the bore-hole as steam and the like soon exceeds the energy recovered as oil. Substantial technical breakthroughs in low-cost recovery techniques appear unlikely.

### Conclusions

29. This discussion has deliberately ignored many complexities of oil, including the blending requirements of refineries, the relationships of demand for various refined products, the methods of refining various crudes into various proportions of different products, the public-health constraints imposed by the sulphur content of various crudes, the uncertain status of desulphurizing and stack-gas-cleaning technologies (now being rapidly deployed in Japan), the growing difficulty of siting refineries in most industrialized countries; the consequent industrialization of, for example, the Caribbean area, the cost and side-effects of marine transport through congested shipping lanes (oil is the world's largest shipping commodity by tonnage); and the possibility that oil may become more important for its molecular structure than for its heat content (e.g., more important as a petrochemicals feedstock or as a sub-

<sup>32</sup> M. K. Hubbert, *loc. cit.*

<sup>33</sup> J. E. Adkins, "Oil crisis: this time the wolf is here", *Foreign Affairs*, April 1973, pp. 462-490.

<sup>34</sup> Among the hidden costs of Middle Eastern oil is the cost of the weapons "needed" to "protect" it—and in turn the need to counter the destabilizing effect of those weapons.

<sup>35</sup> As is remarked in a recent study: "Co-operation between nations is highly desirable, but if undertaken to preserve energy supplies it comes near to conflicting with the unhindered conduct of an independent foreign policy which these secure supplies are partly intended to allow." See I. Fells and others, *Energy for the Future* (London, The Institute of Fuel, 1973). See also "Foreign policy implications of the energy crisis", United States House of Representatives, Committee on Foreign Affairs, Subcommittee on Foreign Economic Policy, 1972. Cynics might identify three main outcomes: (a) Middle Eastern oil is shipped as consumers desire, resulting in excess producer liquidity (see J. E. Adkins, *loc. cit.*), local economic and political instability and war; (b) oil shipments are restricted, leading to economic disruption of, and military adventures in the Middle East by, consumers and hence to war; (c) consumers strive to ensure that they won't care whether they get the oil or not; for Western Europe and Japan, that day is far off.

<sup>36</sup> These figures are derived from a graph in a report by the Norwegian Government, report No. 51 (1972-1973), presented as part of a Ministerial briefing on oil landings. They have since been confirmed independently.

<sup>37</sup> Those arguments not yet mentioned include retaining a bargaining counter (North Sea oil no longer fills this role once extraction has begun), saving domestic reserves for the time when world prices are highest and suppliers least amiable, minimizing social and environmental disruption, evolving safer technologies and a healthy indigenous support-industry, reducing the duplication of costly facilities and the temptation to put them in inappropriate places, developing needed technical and managerial expertise at home and stretching social benefits. The two critical questions to ask are: whether oil in the ground is the best investment and what will be done for an encore.

<sup>38</sup> H. Perry, *op. cit.*

strate for single-cell protein production than as a fuel). These complexities do not, however, affect the general structure of the world oil problem: cheap oil, for long far too cheap, has now become so highly localized that it will not remain cheap—nor, on a time-scale of a few decades, plentiful. The landed prices of Middle East crudes in the EEC and in the United States, already rising steeply even before the war in 1973, will probably rise from two to four times within the next decade. Developing countries struggling to expand nascent industry will be most seriously affected. Such high prices do, of course, open up many newly competitive options; but these options take so long to develop and deploy that oil prices will go far to determine energy prices, no matter what cheaper alternatives are available on paper. Some industrialized countries may try simply to pass their extra energy costs on to others by increasing their industrial output—a sort of reverse price elasticity of demand (viable only if all countries could be simultaneous net exporters, or importers, of the same products).

#### NATURAL GAS

30. Natural gas, unlike oil, is an exceptionally clean and convenient premium fuel, the use of which for low-grade purposes (e.g., raising steam) will probably be banned in most countries within a few years. The energy content of ultimately recoverable world resources is of the same order for gas as for oil, with which it tends to be geologically associated (though decreasingly so as gas exploration techniques improve). However, cheap reserves of gas may be slightly closer to depletion than those of oil because growth in demand, despite a somewhat later start, has been more rapid. (In the United States of America, for example, a very low fixed gas price had stimulated a huge artificial market which soon encountered several years ago the practical limits of domestic production rates. Gas currently provides one third of the energy and is the sixth largest industry in the United States.)<sup>39</sup> The Soviet Union apparently holds about one third of ultimately recoverable world gas resources, and North America and the Middle East about one fifth each.<sup>40</sup>

31. Gas is far more costly to transport overseas than oil. Massive efforts are currently under way to augment pipelines and the like, with liquefied natural gas (LNG) marine carriers, in order to export more gas from surplus to deficit areas (mainly Japan and the United States) and to help eliminate the flaring that still wastes a substantial fraction of gas production. This extremely expensive and demanding technology is examined below; it may only be mentioned now that its advocates

<sup>39</sup> S. D. Freeman, "Toward a policy of energy conservation", *Bulletin of the Atomic Scientists*, vol. 27, No. 8 (October 1971), pp. 8-12.

<sup>40</sup> The natural-gas liquids, produced together with natural gas, and subject to similar supply constraints, are not explicitly treated here. Consisting of *n*-paraffins with more than two carbon atoms, they are generally about one fifth as plentiful as crude oil, with which they may be aggregated as "total petroleum liquids".

expect it to grow 40-45 per cent per annum during this decade and over 7 per cent per annum thereafter.

#### Commitments to premium fuels

32. Short-term planning by major petroleum consumers has led to heavy and hard-to-reverse commitments of capital: e.g., some 200 million motor-cars, each burning roughly its own mass in fuel each year with about 10-20 per cent efficiency.<sup>41</sup> This world motor-car fleet, officially projected to double by 1985,<sup>42</sup> consumes as fuel about 6 per cent of all world energy (two thirds of it in the United States, where the cars are twice as large as elsewhere) and about one eighth of world oil production (close to half of the crude oil consumed by the United States).<sup>43</sup> The total energy cost of motor-cars, including, *inter alia*, roads, factories, sales and maintenance, is very much larger.<sup>44</sup> Such a politically sensitive commitment, reflected in urban and social dependence, conflicts with resource constraints that will become acute within the lifetime of motor-cars now on the road and with other politically sensitive side-effects (e.g., marine oil-spills, refinery nuisance and air pollution). Yet, the dangers of short-term transport planning still seem remote to many Governments—even in the EEC and Japan, which currently depend upon imported oil (mostly from the Middle East) for about two thirds of their energy, but which are making little effort to restrict premium fuels to non-substitutable uses.<sup>45</sup>

33. Short-term fuel planning can be very costly, not least in the lifetime of associated capital. As Carroll Wilson writes:

"The painful fact is that some part of total refinery capacity, and as much as half of the planned superport capacity, will become obsolete or surplus as we carry out the shift to coal and the reduction in the proportion of our energy needs supplied by oil imports. When a problem has been neglected as long as we have ignored or misjudged the energy situation, the short-term requirements may not mesh with the requirements for the medium and longer term—and so it is in this case. We have to fix the roof and build a new house at the same time."<sup>46</sup>

#### COAL

34. Fortunately, world fossil-fuel resources are not limited to oil and gas. Coal and lignite resources which

<sup>41</sup> H. Perry, *op. cit.*; S. D. Freeman, *loc. cit.*

<sup>42</sup> G. Leach, *The Motor Car and Natural Resources* (Paris, Organisation for Economic Co-operation and Development, 1972).

<sup>43</sup> *Ibid.*

<sup>44</sup> Input-output analysis of energy consumption in the United States of America in 1963 puts the total for motor-cars at over 29 per cent. See R. A. Herenden, document No. 69, Center for Advanced Computation of the University of Illinois, Urbana, Illinois, United States of America. Estimates of the 1973 figure range upwards by as much as two times.

<sup>45</sup> This is one of the most important steps needed. See I. Fells and others, *op. cit.*

<sup>46</sup> C. L. Wilson, "A plan for energy independence", *Foreign Affairs*, July 1973.

are an order of magnitude larger—two thirds of them in Asia—await proving and extraction. Roughly 56 per cent of the ultimately recoverable coal resources of the world are in the Soviet Union and Eastern Europe, 20 per cent are in the United States, 8 per cent are in Canada, 5 per cent are in Western Europe, 1.4 per cent in Africa, 0.8 per cent in Oceania and 0.18 per cent in Central and South America.<sup>47</sup> Much of the more accessible coal will cost tens of percentage points more than the coal currently used because of higher transport cost and the capital cost of new railways and pipelines; and not all of the cheap coal has conveniently low levels of sulphur and ash. World resources of solid hydrocarbons recoverable at costs probably within a factor of from two to three of that of today are sufficient to meet projected world demand for 200-300 years,<sup>48</sup> though this lifetime would drop to about a century if, as appears likely, large amounts of coal were converted to synthetic fluid fuels to make up for oil and gas shortages. (The complexities of, for example, coal needs for primary metallurgy, sulphur and ash content and methods of transporting coal need not be of concern on such a time-scale.)

#### *Side-effects*

35. The bulk of cheap coal and lignite reserves can be extracted only by surface mining on a very large scale.<sup>49</sup> Long-term restorative technology, still in a rather primitive state in most countries,<sup>50</sup> may not be able to prevent eventual dereliction of fragile areas, though it should succeed in many others. Steep or arid land probably cannot be restored; elsewhere, great diligence and rigorous enforcement may be necessary.<sup>51</sup> Growing resentment at past despoliation and at such side-effects as acid drainage may be expected to make large-scale coal-stripping politically awkward in such areas as the western part of the United States of America. The social costs of coal-mining, especially underground, are also high, though they could be much reduced: a recently opened deep mine in Illinois is said to use every kind of safety and health precaution known, yet it is still profitable. Highly or fully automated underground mining can probably be made as economical as traditional labour-intensive methods,<sup>52</sup>

<sup>47</sup> M. K. Hubbert, *loc. cit.* (People's Republic of China not included.)

<sup>48</sup> *Ibid.*

<sup>49</sup> This generalization must be heavily qualified if "cheap" is broadly construed. If one assesses resources ultimately recoverable at any price, then most of the coal and lignite is probably deep. In the United States of America, for example, only about one fourth of reserves and one twentieth of resources are strippable—still, of course, an enormous amount of coal.

<sup>50</sup> The Federal Republic of Germany and the United Kingdom of Great Britain and Northern Ireland appear to be the most advanced. In the United Kingdom, costs for restoration to grade B farm land often run about £0.58 per square metre plus overheads.

<sup>51</sup> See the forthcoming report by the National Academy of Sciences/National Research Council on restoration problems in the western part of the United States of America.

<sup>52</sup> M. W. Thring (Queen Mary College, London) estimates that the automated "mechanical mole" approach he has long

and must be a high research priority in many industrial countries. On the whole, it seems likely that an extensive clean up of coal technologies, embracing both mining and combustion,<sup>53</sup> would add only tens of percentage points to current costs. Devising such steps to minimize social and environmental costs of coal is an especially urgent task because in many industrial countries—including the Soviet Union, the United Kingdom and the United States—coal is the bridge from the oil/gas to the energy-income economy. The responsible and orderly expansion of coal production is subject to unknown rate constraints, but they are probably not formidable. It will be much easier if the industry deploys coal technologies that are much more sophisticated than those currently widely used. It is a *sine qua non* for a sustainable energy economy in many countries, and would be a more efficient and long-lived use of capital than most petroleum investments.

#### *Fuel policy*

36. The timing of shifts from petroleum to coal is controlled in part by private-sector market forces too subtle to explore here. It is noteworthy, for example, that nearly all of the viable elements of the coal and uranium industries, part of the nuclear component industry and most of the known geothermal resources in the United States are already controlled by the oil industry—which will also soon control the new coal-conversion industry. Throughout the world, corporate integration is producing energy firms with strong monopolistic tendencies. This "diversification" is logical from the point of view of the firms: they develop coal conversion because they have the money and geothermal power because they have the drilling technology. The implications for a competitive market-place, however, may be equally logical and rather less constructive.<sup>54</sup> It is not clear that the United Kingdom, with nationalized coal, is really better off, for the preferences of a monopoly consumer (such as the nationalized electricity industry) can, and do, turn the price structure of principal fuels upside-down.

---

advocated could, if fully developed, cost perhaps half as much as conventional underground methods.

<sup>53</sup> A potentially limiting hazard in coal combustion, especially with coal of high ash content, is the release of large numbers of submicron particles (1 micron =  $1 \mu = 10^{-6}$  m). Such particles are very difficult to recover and can be synergistic with other emissions in their effects on public health. This problem deserves close study. The baroque approach now used for such awkward emissions as oxides of sulphur and nitrogen—passing them on to neighbours through a tall stack—is no longer good enough, as current studies of acid rainfall in Scandinavia are expected to show. It is all the less suited for submicron particles, which can have very long atmospheric residence times.

<sup>54</sup> Somewhat different institutional pressures in the Federal Republic of Germany are now leading to the flooding of marginal coal-mines—an effective way of burning bridges behind the nuclear power programme. Still another face of the same problem is the weakness of many national Governments in the face of multinational oil companies with considerably larger turnover than the gross national product of all but the richest countries.

37. A brief review of the proximate causes of current (prior to the war in 1973) energy shortages in the United States may help to illustrate the failures of fuel planning that are rapidly jeopardizing stable energy supplies all over the world. Errors of management by the United States have included:

(a) Natural-gas prices that were too low and that destroyed "stretch" in productive capacity. (In consequence, prices must probably treble in this decade);

(b) Oil-import quotas that eliminated a strong reserve position: oil production in the United States has already passed its peak, and the shift from being the world's largest exporter to being the world's largest importer will be the most massive in current or future energy trade;

(c) Stoppage of refinery construction for environmental and economic reasons; inadequate control over refinery operation;

(d) Premature commitment of electric utilities to nuclear power;

(e) Systematic neglect and running-down of the coal industry, even though, on official projections in the United States coal consumption is to treble by 2000. (Since the Oyster Creek contract<sup>55</sup> was signed a decade ago, no new coal-mine has been opened anywhere in the United States without a prior long-term contract for selling the output);

(f) Heavy reliance of electric utilities on premium fuels;

(g) Generally low energy prices which, coupled with the attitude that there will always be a surplus of cheap energy, has led to extravagant use;

(h) Failure to anticipate and forestall the consequences of the above-mentioned policies by appropriate research and development; e.g., sophisticated coal technologies must now be imported or improvised because there is almost no domestic technical base, most of the money having gone into development of fast breeder and other fission reactors. Coal gasification can therefore make no large impact before the late 1980s;<sup>56</sup>

<sup>55</sup> This fixed-price contract for a nuclear power-station was regarded as the first breakthrough into competition with coal. In the event, the station was commissioned two years late at a cost overrun of 32 percent. The utility's next order for the Oyster Creek site was postponed in favour of a coal-fired station.

<sup>56</sup> Synthesizing liquid and gaseous fuels from coal on a large scale will be neither cheap nor easy, though it can certainly be done at a cost—perhaps, for high-BTU gas, about four to five times the current pipeline cost. The processes, particularly for high-BTU gas, are still in preliminary development, with several methods being pursued at once. Construction of production plants could begin in a few years if a high-cost, high-risk programme of parallel pilot and demonstration plants were launched now. Equally important is the development of much better technologies for burning coal: fluidized-bed combustion, a promising approach being studied in the United Kingdom and elsewhere, could be rather widely deployed in the 1980s. On coal technologies in general, see H. C. Hottel and J. B. Howard, *New Energy Technology—Some Facts and Assessments* (Cambridge, Mass., Massachusetts Institute of Technology Press, 1971); and D. A. Berkowitz and A. M. Squires, eds., *Power Generation and Environmental Change* (Cam-

(i) Failure to identify and regulate gross misuses of energy, including electric space-heating; absolute rejection of energy conservation;

(j) Failure to maintain an adequate data base for future policy decisions;

(k) Failure to evolve a suitable institutional base; about 64 agencies of the federal Government now share jurisdiction over energy policy in the United States.<sup>57</sup> Similar errors have occurred and are continuing to occur in the United Kingdom and in most other industrial countries, where many of the decisions governing energy supply in the mid-1980s have already been taken, as a rule in a long-term policy vacuum.

#### "UNCONVENTIONAL" HYDROCARBONS

38. Up to this point, no reference has been made to two possible sources of reduced carbon: tar-sands, principally in Alberta (Canada); and oil-shales, principally in Colorado and Wyoming (United States of America), in South America and, perhaps, in Asia.<sup>58</sup>

#### *Tar-sands*

39. The Athabaskan tar-sands of Alberta, in limited production since 1966, are about to enter large-scale production for United States markets. World resources are approximately from one fifth to one seventh those of liquid petroleum and are, on average, more (though not prohibitively) costly. It appears unlikely that tar-sand products will be exported from North America.

#### *Oil-shales*

40. Oil-shale resources—under pilot study for several decades in the western part of the United States of America—are potentially far larger than total world oil resources, but only if one incurs extreme costs by including submarginal shales so poor that the difficulties of production (including waste disposal) seem insuperable.<sup>59</sup> One can now envisage the economic recovery of only about one ten-thousandth of the total, equivalent to an order of magnitude less than world crude-oil resources. High-grade oil-shales, which are about 10-20

bridge, Mass., Massachusetts Institute of Technology Press, 1971).

<sup>57</sup> United States of America, Ninety-third Congress, Senate, Committee on Interior and Insular Affairs, *Federal Energy Organization*, Serial 93-6 (92-41) (Washington, D.C., Government Printing Office, 1973).

<sup>58</sup> M. K. Hubbert, *loc. cit.*

<sup>59</sup> On 23 November 1973, a major oil company announced its technique for *in situ* retorting, said to cost \$1 per barrel in a 25-30 barrel-per-day pilot plant. Extrapolations of this operating cost (from one third to one fifth the technical unit cost suggested above) to an operation 100,000 times or more larger are speculative. Such an operation would, as the oil company agrees, require capital beyond the capacity of the oil industry to supply and would be rather slow to create. The euphoria with which *The Times* of London announced the pilot-plant results on 24 November (with a quarter of the front page plus a leader entitled "Two million million barrels at one dollar a barrel") is thus not only premature, but somewhat irresponsible. The process does not appear to affect the validity of the oil shale assessment in this paper.

per cent hydrocarbons by weight, are difficult and expensive to process; are often under several metres of overburden; occur mainly in arid regions where water-supply<sup>60</sup> and run-off water quality severely constrain production; produce very large amounts of intractable waste rock; and yield an oil that may require special refining methods and equipment. There is no general agreement that oil-shale will ever become an important energy source, though minor production seems possible in the few regions possessing such reserves.

41. One leading authority concludes that the shales "appear to be more promising as a source of raw materials for the chemical industry than as a major source of industrial energy".<sup>61</sup> Compared with the latter course, production of low-sulphur liquid and gaseous fuels from coal seems cheaper, easier and far nearer practicability,<sup>62</sup> despite its inherent inefficiency, and can be expected to compete very effectively under any foreseeable price régime. (Materials-handling problems are less with coal conversion than with shale because the energy yield per ton is about four times as large.) There is also no doubt that world coal resources, though unevenly distributed, suffice to support at least a century of intensive world industrial activity, if the technical and political obstacles to their large-scale extraction and distribution can be overcome.

#### RATE AND MAGNITUDE PROBLEMS

42. The physical resource base, however, is not the whole story. It is hard to think of any thoughtful student of the fossil-fuel industries who believes that as world population doubles,<sup>63</sup> say, by the first decade of the next century, world energy conversion will increase six times (as current growth rates suggest). Even if the technical, environmental, political and institutional difficulties of such an increase could be mastered, the rate and magnitude problems appear to be well beyond the capacity of world industry and finance—especially if they are to be devoted to other problems as well. In the author's view, the world would be hard-pressed to produce half that much growth in the same period, particularly since world crude-oil production will undoubtedly peak within a generation. A mere doubling of world energy conversion will be hard enough.

<sup>60</sup> For its requirement of, perhaps, 1-2 m<sup>3</sup> per barrel; an oil-shale industry can be expected to compete very effectively with local irrigators.

<sup>61</sup> M. K. Hubbert, *loc. cit.*

<sup>62</sup> Coal conversion is water-intensive, but of the nearly 200 identified sites in the United States with enough water and coal, some ought to be socially and environmentally suitable; this is likewise true abroad. The side-effects of coal conversion are speculative, but probably manageable. Some conversion schemes use a combined power-cycle yielding both process heat (for the conversion) and electricity. The complexities of high- versus low-BTU gasification need not be of concern here, though the former, yielding gas of pipeline quality, would be more useful for basic shifts in energy supply over large regions.

<sup>63</sup> This assumes, for the sake of argument (and prudence), that world population will in fact double, i.e., that food supply will at least do likewise, which the author considers very unlikely.

43. Indeed, the exponential growth of energy conversion in any industrialized country (excluding such special cases as Norway) is the sum of a series of overlapping exponential curves representing new energy sources, each introduced as the preceding curve matures or begins to falter, and each, in general, of a simpler character than those preceding. Thus, coal displaced wood, and was in turn displaced by oil and by gas (the latter, with its exceptional simplicity, accounting for two thirds of energy growth in the United States from 1945 to 1965). In most countries, domestic supplies of oil are, in turn, being supplemented by imported oil; and in some, gas by imported gas (LNG). Continued exponential growth of total energy conversion requires that each successive source be capable of more rapid growth than that preceding it—possible only if there is a very large existing energy inventory capable of being cheaply and rapidly mobilized, as was historically true of oil in the Persian Gulf and natural gas in the United States of America.

44. Governments have apparently acceded to quick depletion of cheap energy reserves on the tacit assumption that a new source will turn up in time to maintain ever faster growth. The most recent such innovation, however, is nowhere in sight; and a little reflection about the character such a new source must have makes clear the reason. Nuclear power, with its complexity and long lead times, is far too slow. Existing energy industries are thus under severe stress to try to make up a growing deficit. (In the United States of America, for example, gas and oil fields—and the refineries of the major producers—are operating at 100 per cent, or somewhat more, of their nominal maximum capacities.) This stress is in a sense due, as is often said, to a temporary shortage (of, e.g., refinery capacity) caused by prolonged mismanagement; but the underlying problem is real and will not go away.

#### NON-FOSSIL-FUEL OPTIONS

45. It is therefore time to examine the short-, medium- and long-term options that energy technologies not based on fossil fuels may offer. These options are of a character ranging from exceptionally simple to exceptionally complex; and it is here, in the realm of potential innovations, that the political, environmental and social side-effects of new technologies need the most careful assessment, bearing in mind the very different needs and aspirations of different cultures. It is easy, for example, to fall into the trap of assuming that a particular technology is insignificant on a world scale because it can supply only, say, 1 per cent of world energy needs. What matters is not aggregate energy production, but the ability of a technology to meet the energy needs of people in particular circumstances. A highly diffuse, low-intensity energy source might be ideal for a dispersed rural population. It would be imprudent for even the most highly urbanized and industrialized countries to assume that they will

not or should not have substantial populations in this circumstance.

## NUCLEAR FISSION

46. The promised innovation upon which most energy planners have relied for the past two decades, apparently without considering how rapidly it can be deployed, has been nuclear fission—the extraction of heat from fissile (or, indirectly, from fertile) isotopes. This technology has received an enormous amount of highly skilled and dedicated attention for several decades. Yet, the United Kingdom, the country now most heavily reliant on fission, generates only a tenth of its electricity in this way; and in the United States, after 25 years and thousands of millions of dollars spent in research and development, nuclear power has only just surpassed fire-wood<sup>64</sup> as an energy source. Indeed, it was not until 1971 that the total electricity production of all nuclear power-stations in the United States exceeded the electricity consumption of the gaseous-diffusion plants used to enrich uranium. In short, nuclear power has been very slow in arriving. Nevertheless, its advocates claim that it is poised for a remarkable spurt of growth with a doubling time of the order of a few years—sufficient to take over the role of faltering gas production in maintaining the world energy doubling time of about 12.5 years. Most energy planners share this view.

47. Limited but acrimonious public debate over whether this is possible or wise has exposed a deep division of opinion within the scientific community over fundamental technical and moral issues raised by nuclear fission. Because this controversy is so crucial to any assessment of future energy supply, it is worth analysing at some length. If the present summary seems critical, however, no reflection is intended on the motives of anyone engaged in promoting or developing nuclear fission. Decent, sincere people, perhaps caught up in the momentum and the intense social pressures of a committed organization, naturally like to think that what they are doing is worth while, and are not always so concerned with gaps between intention and performance.

### Issues

48. The problem of evaluating fission technology has been well stated by Kneese:

“It is my belief that benefit-cost analysis cannot answer the most important policy questions associated with the desirability of developing a large-scale, fission-based economy. These questions are of a deep ethical character. Benefit-cost analysis cer-

<sup>64</sup> Fire-wood provided three quarters of the energy in the United States of America in 1870, when the population of the country was one fifth of the current total and energy conversion *per capita* was two sevenths. (See S. D. Freeman, *loc. cit.*) Some observers believe that contribution of wood is underestimated and still exceeds that of fission.

obscure them. . . .

“[T]he advantages of fission are much more readily quantified in the format of a benefit-cost analysis than are the associated hazards. Therefore there exists the danger that the benefits may seem more real than the hazards. We are speaking of hazards which may afflict humanity many generations hence, and distributional questions which can neither be neglected as inconsequential nor evaluated on any known theoretical or empirical basis. This means that technical people . . . cannot legitimately make the decision to generate such hazards on the basis of technical analysis.”<sup>65</sup>

Kneese is arguing, then, not merely that the benefits and risks of fission technology have been insufficiently quantified to support a benefit-cost judgement, but, further that such a judgement could not be technically valid. It is appropriate here to explore the reasoning behind this opinion.

49. The very large inventories of fission and activation products in the nuclear fuel-cycle give rise to risks<sup>66</sup> unlike those of any other single technology. These risks combine the geographical range of military pathogens, the permanence of irreversible changes in climate or in soil fertility and the medical and moral significance of the most persistent synthetic mutagens. Because the unique hazards of nuclear fission depart so much from man's experience, before one chooses to incur those hazards one must define, with special care, the limits of man's ability to cope with them.

50. Most fission technologists realize that they are creating new categories and magnitudes of risk, and they respond with clever precautions. But by stressing the great care that they take, fission technologists evade the central question—whether the safety problems of fission are too difficult to solve. If they are, then one cannot claim that they are solved by pointing to all the efforts made to solve them.<sup>67</sup>

### *An engineering problem or a people problem?*

51. It is impossible to prove, except by experiment, whether the safety problems of widely proliferated fission technology are too difficult to solve. In assessing the risks of a complex technology in which “no acts of God can be permitted”,<sup>68</sup> one can only rely on analogies with other highly engineered systems that have risks several orders of magnitude smaller and quite different in kind. Such analogies suggest that safety in nuclear fission is ultimately limited, not by man's care or ingenuity (as has been true of all previous technol-

<sup>65</sup> A. V. Kneese, “What will nuclear power really cost?”, *Not Man Apart*, vol. 3, No. 5 (May 1973), p. 16. Based upon testimony at the hearings of the United States Atomic Energy Commission on the nuclear fuel cycle, November 1972.

<sup>66</sup> For an excellent topical assessment, see D. F. Ford and others, *The Nuclear Fuel Cycle* (Cambridge, Mass., Union of Concerned Scientists, 1973).

<sup>67</sup> H. Alfvén, “Energy and environment”, *Bulletin of the Atomic Scientists*, vol. 28, No. 5 (May 1972), pp. 5-7.

<sup>68</sup> *Ibid.*

ogies),<sup>69</sup> but by his inescapable human fallibility: limited not by man's ability to solve problems on paper, but by his ability to translate paper solutions into real events. If this view is right, then nuclear safety is not a mere engineering problem that can be solved by sufficient care, but rather a wholly new type of problem that can be solved only by infallible people. Infallible people are not currently observable in the nuclear or any other industry.

52. International experience at many stages of the nuclear fuel cycle supports the thesis that describing nuclear safety problems as "amenable to engineering solution" confuses the way things are with the way one would like them to be. This experience shows that people have impressive talents in overcoming foolproof systems and suggests that catastrophes have so far been averted more by luck than by design.

53. Fallibility will find its greatest scope for expression in three exercises: containing radio-isotopes within the nuclear fuel cycle, containing them after they have been rejected as wastes and containing strategic materials. Such "fallibility problems" can be expected to become more prominent as reactors proliferate, investment conquers caution, boredom replaces novelty, routine dulls commitment and less skilled technicians take over (especially in countries with "comparatively low levels of technological competence and a great propensity to take risks").<sup>70</sup> The third of these problems—perhaps the most critical—is discussed below, together with some risks of non-nuclear energy technologies; the other two are briefly discussed here:

(a) Failure of containment appears to be most likely in three phases of the fuel cycle:

(i) *Reactor operation* (where radio-active inventories are of the order of  $10^{10}$  curies<sup>71</sup> and where the consequences of a failure could include 10,000 or more deaths, numerous injuries of widely varying induction time and property damage of the order of £10<sup>10</sup>). Failure may be induced by disruptive energy releases (chemical or nuclear), mechanical or cooling faults, acts of war or sabotage. The last two of these risks, the difficulty of decommissioning, and perhaps the magnitude of potential radio-active releases in any accident<sup>72</sup> could be much reduced by under-

ground siting. This procedure would cost about the same<sup>73</sup> but has attracted almost no official interest,<sup>74</sup> despite the likelihood that "fission plants will be enormously attractive objects for sabotage and blackmail."<sup>75</sup> Alternatively, risks can be greatly increased by raising power density, as in large light-water reactors<sup>76</sup> or in fast-breeder reactors (~400 kW/litre).<sup>77</sup> The disposition, during an accident, of a fast breeder's fissile inventory (including <sup>239</sup>Pu<sup>78</sup> equivalent to about 100 bare-sphere critical masses) cannot be predicted for a partially molten core affected by sodium flow or compression waves. It is difficult to see how any convincing assurance against a Bethe-Tait accident (critical reassembly) can be

<sup>69</sup> F. C. Rogers, "Underground nuclear power plants", *Bulletin of the Atomic Scientists*, vol. 27, No. 8 (October 1971), pp. 38-41; B. J. Smernoff, "Underground siting of the LMFBR demonstration plant: a serious alternative", Croton-on-Hudson, N.Y., Hudson Institute, 1972. See also Aerospace Corp. ATR-72 (S7263)-1, March 1972. Environmental Quality Laboratory Report No. 6; and ORNL SD-71-66 (R)-5872, Oak Ridge National Laboratory, August 1966.

<sup>74</sup> In the United States of America, the Atomic Energy Commission recommended it to the President in 1962. The proposal sank without trace, presumably because awkward questions might be asked about reactors already built on the surface.

<sup>75</sup> J. T. Edsall, letter to the editor, *Science*, vol. 178 (1972), p. 933.

<sup>76</sup> It is often claimed that the probability of major component failures in these reactors is extremely low; but that is not really known. The contrary is suggested in United States of America, Atomic Energy Commission (USAEC), *Reactor Operating Experiences*; and in R. L. Scott, "Safety-related occurrences in nuclear facilities", report ORNL-NSIC-91, 1970. The USAEC report WASH-1250, July 1973, estimates that the probability of primary coolant pipe rupture might be about  $10^{-3}$  per reactor-year and that of emergency coolant injection  $10^{-2}$  per demand—clearly intolerable levels. (A senior USAEC official has estimated that a mature nuclear economy in the United States could expect a major reactor accident about every decade.) But designers and accident analysts are also fallible. "Incredible" incidents in which many redundant systems have failed simultaneously ("common-mode failure"), or in which safety systems have interfered with each other, show that accidents can follow courses never foreseen. Thus, it was discovered recently that the USAEC "design basis accident" for emergency core cooling systems is less likely than several other types of accidents, potentially more serious, which the emergency systems could not handle. Such considerations led Ralph Lapp, in his testimony on 23 March 1972 to the Bethesda rule-making hearing (USAEC RM-50-1), to conclude that "the reliability of 'defense in depth' is still in question".

<sup>77</sup> High power density and high plutonium content mean shorter thermal and neutron-physics time constants, placing a heavy burden on control systems and on any negative coefficients of reactivity. Large stresses and high temperatures also aggravate metallurgical or geometric faults in materials whose long-term behaviour under extreme neutron flux is still mainly conjectural.

<sup>78</sup> Plutonium-239 is an artificial radio-isotope with a half-life of 24,400 years. It is made by bombarding uranium-238 (<sup>238</sup>U) with neutrons. It is pyrophoric and reactive, is a hard alpha emitter; is a bone-seeking poison similar to radium, but several times as toxic and is one of the most hazardous substances known. Its most hazardous form may be the respirable dioxide particles produced by combustion—of order  $10^{10}$  particles per gram of metal, with each particle suspected of carrying a substantial risk (perhaps 1 per cent or more) of lung cancer. The plutonium in breeder reactor fuel is already oxidized into a refractory ceramic which, it is claimed, cannot produce respirable particles. It appears plausible, however, that, in an accident, the sodium coolant in a breeder should be easily reactive enough to reduce the dioxide fuel back to plutonium metal. Current breeder safety analyses do not appear to take this possibility into account.

<sup>69</sup> Save, perhaps, manned space flight. In *The New Yorker*, 11 and 18 November 1972, H. S. F. Cooper, Jr., gives a fine account of the impact of human fallibility on a highly engineered system (Apollo 13). It has also been stated that "three astronauts were incinerated due to a very straightforward accident in an extremely high-technology operation where the utmost precautions were allegedly being taken". (See A. V. Kneese, *loc. cit.*)

<sup>70</sup> A. V. Kneese, *loc. cit.*

<sup>71</sup> One curie =  $3.7 \times 10^{10}$  disintegrations per second, roughly the activity of a gram of radium; limiting body burdens of the more dangerous radio-isotopes are typically measured in millionths of a curie or less.

<sup>72</sup> It is often assumed that impermeable rock is a sufficient bar to the escape of volatile and semi-volatile fission and activation products after a core meltdown. This is not necessarily the case. Small or slow leakages are important; shafts must somehow be infallibly sealed; and contact with moisture would evolve prodigious quantities of steam, hydrogen, etc.

given.<sup>79</sup> Super-prompt criticality, resulting in a substantial nuclear explosion, is probably much less likely than a low-yield disassembly—a nuclear fizzle—sufficient to breach containment and release the transuranic and fission-product inventory. There is virtually no limit to the size of the catastrophe that this mechanism could produce;

(ii) *Transport of irradiated fuel.* It is impossible to design a shipping cask that can withstand all accidents, let alone sabotage. Risks will increase with proliferation, especially with a <sup>239</sup>Pu economy. The United States of America envisages 100 railway shipments daily; a single fast-breeder fuel discharge would contain 500 million curies of activity and emit 1.7 MW of heat;

(iii) *Reprocessing of irradiated fuel.* Excluding criticality accidents, internal energy release is less likely here than in a reactor; but the containment is generally less, and the radio-active inventories and concentrations are vastly larger. A more lethal target for acts of war or acts of God can hardly be imagined: a major release could make large regions permanently uninhabitable. The <sup>239</sup>Pu inventory of 1-3 tons in a fast-breeder reactor poses a formidable containment problem because of its extreme toxicity. A lethal dose for everyone on earth could probably be contained in a piece the size of an orange. World inventories are planned to rise rapidly from a few tens of tons now to hundreds of tons in the early 1980s and thousands several decades hence. Some radio-isotopes mobilized by the nuclear fuel cycle, e.g., <sup>226</sup>Ra and its decay products (released in uranium mining and milling), deserve, but seldom receive, proper containment;

(b) High-level wastes emerging from the nuclear fuel cycle can be converted from corrosive solutions to stable solids with technologies currently in hand. This rational precaution will reduce the risks of temporary storage, but brings the world no closer to discovering a method of permanent disposal—of perpetual and infallible isolation from the biosphere. The volume of highly active material requiring such disposal is still relatively small, but is growing rapidly (to an order of 10<sup>11</sup> curies by 2000), and its potency per unit volume is very great.<sup>80</sup> The lifetime of that potency—of the order of 1,000 years for fission products and 1,000,000 years for transuranic activation products<sup>81</sup>—subjects any

terrestrial disposal scheme to geological requirements of which man has no experience and for which no responsible geologist can offer a guarantee. Terrestrial disposal, e.g., in basement rock or in salt beds, must therefore be “retrievable”—and, hence, requires surveillance on a time-scale far exceeding the observed life span of human cultures. Since safe extraterrestrial disposal is neither technically nor economically feasible, one could properly conclude that, as a technical problem, high-level waste disposal is probably insoluble even with large amounts of money; and that as a moral problem, it should be a deep concern. (Disposal of low- and medium-level radio-active wastes—solid, liquid and gaseous—is, perhaps, a less serious problem, but is still very important, especially in cumulative impact, and is seldom dealt with properly.)

#### *Fission economies*

54. It is instructive to contrast with these considerations the proposal of two prominent American energy planners to build 4,000 seaside fission “parks”, each producing 40 GW (e) and nearly twice that much heat, and all producing a total of  $7 \times 10^{11}$  curies per annum of long-lived activity.<sup>82</sup> The fuel would be about  $1.8 \times 10^8$  kg per annum of <sup>238</sup>U and <sup>232</sup>Th, derived from about  $5.5 \times 10^{12}$  kg per annum of granite (about twice the current world consumption of coal) and converted, respectively, to <sup>239</sup>Pu and <sup>233</sup>U. This scheme represents an increase of 50 times in total human energy conversion. The accompanying commitment of humanity “to exercise great vigilance and the highest levels of quality control, continuously and indefinitely”<sup>83</sup> has led some to propose a self-perpetuating “technological priesthood”.<sup>84</sup> Others reply that the required social stability “has not existed in the past, does not exist now and offers no promise of existing in the near future”; that “even devoted priests are human”; and that the importance of the “priesthood” proposal resides in the support it lends to the view that the technical and social problems of the fission economy have no realistic solutions.<sup>85</sup>

55. Though the economics of such an energy increase (50 times) depend upon, and are as speculative as, those of the fast-breeder reactor currently under development,<sup>86</sup> it is important to note, in view of the special

---

scheme, though perhaps substantial, do not appear to be as large as is claimed.

<sup>80</sup> A. V. Kneese, *loc. cit.*

<sup>81</sup> A. M. Weinberg, “Social institutions and nuclear energy”, *Science*, vol. 177 (1972), pp. 27-34.

<sup>82</sup> J. T. Edsall, *loc. cit.*

<sup>83</sup> A. B. Lovins, in *Hearings on the LMFBR demonstration plant*, United States Congress, Joint Committee on Atomic Energy, 8 September 1972, pp. 120-130; excerpted, “Case against the fast breeder reactor”, *Bulletin of the Atomic Scientists*, vol. 29, No. 3 (March 1973), pp. 29-35. A forthcoming survey by T. C. Cochran (Resources for the Future, 1974) goes into far greater economic detail. The breeder programme in the United States is now well known to be in such economic trouble that *The New York Times* could comment editorially (30 October 1973): “The drawbacks of the breeder, its

(Continued on next page)

<sup>79</sup> Elaborate computer calculations have been made of the course of disassembly after assumed reassembly accidents. Basic physical understanding of the course of reassembly, however, is inadequate for the task and has progressed scarcely at all in the past two decades.

<sup>80</sup> The volumes involved are sometimes referred to in reassuring units such as matchboxfuls *per capita*. The risk associated with such seemingly small amounts, however, is altogether foreign to common experience; see the remarks about plutonium toxicity in footnote 78.

<sup>81</sup> D. J. Rose and A. S. Kubo (Nuclear Engineering Department, Massachusetts Institute of Technology), in a useful paper, “On disposal of nuclear wastes” (to be published), discuss the separation of these two categories so that the actinides can be burned in a reactor. The practical advantages of such a

hazards of fast-breeder technology<sup>87</sup> and of the <sup>239</sup>Pu economy,<sup>88</sup> that projected populations of thermal (non-breeder) reactors could be economically fuelled for several centuries unaided by any breeder reactors at all. This is because the cost of uranium feed-stock (U<sub>3</sub>O<sub>8</sub>) is only a few percentage points of the sent-out cost of nuclear electricity;<sup>89</sup> hence, the latter is insensitive to the former. An increase of \$1 per pound (\$2.2 per kg) in the price of U<sub>3</sub>O<sub>8</sub> would increase the marginal cost of bulk electricity from a 1-GW(e) pressurized-water reactor<sup>90</sup> by only 0.052 m\$/kWh without, or 0.034 m\$/kWh with, Pu recycle;<sup>91</sup> the cost increase would be less for the consumer, who also pays fixed distribution costs, and should be similar for gas-cooled reactors. Thus, an increase of 10 times in U<sub>3</sub>O<sub>8</sub> price—enough to increase, for example, reserves in the United States by more than 2,000 per cent<sup>92</sup> without requiring environmentally unacceptable mining methods,<sup>93</sup> and, similarly, in many other countries<sup>94</sup>—would increase the bulk price of current nuclear electricity by about 18–27 per cent, trivial compared with increases in other energy sectors.<sup>95</sup>

expense, dangers and complexities even beyond those of today's light-water reactors, have grown more worrisome under less partisan analysis; these reservations have apparently now reached the top echelons of the White House." See also R. Gillette, "One breeder for the price of two?", *Science*, vol. 182, No. 38 (5 October 1973), p. 38. Gillette reports that the capital costs of the demonstration breeder currently exceeds \$12,000/kW (cf. about \$56/kW for a PR). The breeder programme in the United States, like the light-water reactor and nuclear export programmes, is also in serious legal trouble.

<sup>87</sup> A. B. Lovins, *Hearings on the LMFBR . . .*, loc. cit.

<sup>88</sup> Certain logistical details of the <sup>239</sup>Pu economy remain unclear. The core doubling-time of the United States breeder, at simple interest, is about 24 years, in contrast to the British claims of 12 for Dounreay. (Many observers consider the burn-ups and neutron fluxes implied by the latter figure to be rather implausible.) If the pipeline inventory of <sup>239</sup>Pu for a new breeder is only as large as the core inventory, then a United States breeder can fuel another in about 48 years. The breeder populations projected by the United States Atomic Energy Commission for the year 2000, therefore, appear to entail a <sup>239</sup>Pu requirement far too large to meet even if weapons stockpiles are released. Similar questions may arise in other countries with breeder programmes.

<sup>89</sup> C. E. Larson, "International economic implications of the nuclear fuel cycle", United States Atomic Energy Commission speech S-11-72, given 10 July 1972, AEC news release 2 August 1972.

<sup>90</sup> United States of America, Atomic Energy Commission, WASH-1139 (Rev.1), December 1971, p. 10.

<sup>91</sup> C. E. Larson, Commissioner, United States Atomic Energy Commission, personal communication, 2 November 1972.

<sup>92</sup> United States of America, Atomic Energy Commission, "US January 1, 1971 high cost uranium resources—\$30 to \$500/lb U<sub>3</sub>O<sub>8</sub>", unpublished sheet dated "9/1/71". (The methods used by the Atomic Energy Commission in estimating U reserves make it possible that the figures in this sheet may be 10 times or more too low.)

<sup>93</sup> C. L. Bienewski and others, "Availability of uranium at various prices from resources in the United States", United States Bureau of Mines report IC-8501, Washington, D.C., 1971.

<sup>94</sup> Uranium and, for that matter, thorium, are surprisingly widely distributed, though many of the richer deposits are in North America, Southern Africa and Australia. A prominent French official, however, has recently estimated that France alone could supply the U<sub>3</sub>O<sub>8</sub> needs of the European Economic Community for well over a century at about \$40 per pound.

<sup>95</sup> Cost comparisons between fission and fossil-fuel power are meaningless in any case because of strong government

56. Public awareness of the issues raised by nuclear fission is now sufficient to make fast proliferation of this technology difficult in many countries despite its immense political, economic and institutional momentum. Fuelled both by deep and rapidly growing anxiety in the technical community (especially in the United States)<sup>96</sup> and by the obvious need for any re-evaluation to begin at once before the commitment becomes irreversible, public debate will quickly expand and intensify. Rapid shifts in opinion are illustrated by recent actions of official bodies in both the Federal Republic of Germany<sup>97</sup> and Sweden.<sup>98</sup>

57. Perhaps surprisingly, however, the much-publicized delays in reactor commissioning in the United States in the past few years, and the failure of currently planned reactors to meet more than half of the trend projection for the early 1980s, have been due almost entirely to poor management, manufacturing and labour difficulties, poor quality assurance,<sup>99</sup> unexpected technical snags and the other standard problems of rapid high-technology proliferation—not to

"incentives" aiding mainly the former. (Incentives cost the same as subsidies, but sound nicer.)

<sup>96</sup> Warnings have come from such sources as the Rand Corporation, "California's electricity quandary", September 1972; the Federation of American Scientists, *FAS Newsletter*, February 1973; two former top officials of the United States Atomic Energy Commission (USAEC); and scientists and engineers of stature. On 26 October 1973, the Council of the American Physical Society (APS) backed its distinguished working party, which had concluded, after briefings by top USAEC and other safety experts, that APS should conduct a prompt and independent technical study of reactor safety.

<sup>97</sup> On 23 August 1972, witnesses for the Consolidated National Intervenor in the Bethesda ECCS rule-making hearing disclosed a memorandum to Milton Shaw from A. J. Presseski, Assistant Director for Nuclear Safety, Division of Reactor Development and Technology of the United States Atomic Energy Commission, dated 8 May 1972. This memorandum, based on a meeting between Mr. Presseski and Mr. Sahl, head of a technical and regulatory delegation in the Federal Republic of Germany, said that the Reactor Safety Committee (RSK) "has publicly recommended a moratorium on operating licenses until certain ECCS related R&D is performed". The authorities in the Federal Republic of Germany later said that this report was incorrect and due to a misunderstanding by Mr. Presseski. The 1972 *Tätigkeitsbericht* of the Institut für Reaktorsicherheit further reports an indefinite delay in the construction of three boiling-water reactors as a result of the Würgassen accident.

<sup>98</sup> Reported in *Nuclear Engineering International*, June 1973, p. 44; and in principal newspapers. The nuclear trade press later erroneously implied that the Swedish Parliament had not decided to suspend ordering of reactors not already formally committed—i.e., those to be installed after about 1979. Such a ban is in effect until further information is laid before Parliament. This information—now being prepared—will apparently be *pr forma*, but the Parliament appears likely to demand a thorough reassessment instead, so the matter may not be resolved in 1974, as originally expected.

<sup>99</sup> Rand Corporation, *op. cit.*, cites "increasing reports of poor quality control and documented carelessness in manufacture, operation, and maintenance"; many reports of the United States Atomic Energy Commission tell the same story. The result, as the president of Consolidated Edison reported it recently, is that the 18 longest running commercial nuclear stations in the United States averaged 61.9 per cent of their potential output through 30 September 1972. Four approached 80 per cent, but three of these later broke down; eight of the 18 were running at about half capacity.

public resistance or intervention in licensing proceedings (despite very serious doubts<sup>100</sup> about the operating safety of light-water reactors in the United States). It is these former conventional constraints, the rate and magnitude problems stressed earlier, that will prove decisive in preventing fission from meeting projected short- and medium-term demand. Nuclear power does not represent a large reservoir of cheap energy capable of being mobilized very simply and quickly; it is, on the contrary, one of the most complex and unforgiving technologies known to man. Some people still think that nuclear capacity in, say, the United States, will increase 250 times by 2000 and that the equivalent of total current electrical capacity in the United States will then be built every 24 months. There is no accounting for what some people think.

## NUCLEAR FUSION

### Prospects

58. There is perennial speculation, and much misunderstanding, about a nuclear technology whose scientific feasibility, unlike that of fission, remains to be proved (probably in the next decade). Nuclear fusion could be practically free of resource constraints, since the <sup>2</sup>H (deuterium), easily extractable from sea water,<sup>101</sup> represents about 500,000 times the energy content of all fossil fuels. (Lithium reserves, adequate for a few centuries, could also provide an easier thermonuclear reaction.) It is this feature of fusion that has led to many years of research in several technologically advanced countries. It is likely, though not certain, that at least one of several promising approaches<sup>102</sup> will succeed. This could lead to a com-

<sup>100</sup> The depth and basis of these doubts is seldom realized by those unfamiliar at first-hand with the enormous public record of the Bethesda ECCS rule-making hearing (USAEC RM-50-1). This record shows that most of the top safety experts of the Atomic Energy Commission believe there is insufficient technical basis for establishing adequate margins of safety (and hence for licensing the reactors). The public position of AEC on light-water reactor (LWR) safety is flatly contradicted both by the sworn public testimony and by the published internal documents of a very substantial fraction of its own senior staff and advisers, including those at the highest levels. No ordinarily prudent man with full, recent and direct knowledge of the Bethesda record could possibly decide to order light-water reactors. The readiness of many responsible people to do so shows how far the reactor salesmen have outrun not only reactor engineers, but the free flow of information through committed institutions. The best available summary of the Bethesda record is the annotated, semi-technical *Concluding Statement* (Cambridge, Mass., Union of Concerned Scientists, 1972). It is strongly recommended. For political background, see also the four-part series in *Science*, vol. 177 (September 1972), on "Nuclear safety": I, "The roots of dissent" (1 September), pp. 771-772; II, "The years of delay" (8 September), pp. 867-871; III, "Critics charge conflict of interest" (15 September), pp. 970-975; IV, "Barriers to communication" (22 September 1972), pp. 1080-1082.

<sup>101</sup> It is generally assumed that traces of deuterium in sea water have no biological function; nobody really knows.

<sup>102</sup> Magnetic confinement of plasmas is now within about an order of magnitude of the goal. No fundamentally new mistake has been made for several years; on the contrary, some 175 types of plasma instabilities have now been classified. Laser implosion of pellets is conceptually simpler, but poses awkward materials problems. It may also have military implications.

mercial prototype around the last decade of this century, at a cost of the order of £1,000 million, followed by the usual problems of rate and magnitude associated with proliferation. Such a device (whose economics are completely conjectural) will probably be extremely complex, and it seems implausible that the needed technology would be made freely available to all Governments (as the fuel would).

### Side-effects

59. The safety problems of a practical fusion reactor cannot be assessed without building one—a course of action that can be argued to be prudent, if feasible. Sources of disruptive energy release may include strong magnetic fields and large inventories of molten lithium (comparable to the molten sodium in a fast breeder). The reactor could not get out of control nor produce strategic materials.<sup>103</sup> The inventories of radio-active products would be significant (of order 10<sup>8</sup> curies of <sup>3</sup>H); but could, in theory, be recycled as fuel. The main problem would be activation products produced by the intense neutron flux of the reactor, comparable to that in the core of a fast breeder. The theoretical biological significance of these products<sup>104</sup> may, on current estimates, be an order of magnitude smaller than in a comparable fission reactor. Unless it is many orders of magnitude smaller than that—which is possible, but not yet plausible<sup>105</sup>—fusion does not represent an attractive long-term energy source, though in the medium term it is almost certainly preferable to fission. One could argue, further, that if fusion turned out to be a clean, cheap and safe energy source,<sup>106</sup> man would lack the discipline to manage it so as to prevent serious ecological and climatic damage. This topic is discussed later in this paper. Recent history does not say much for man's responsibility in managing large stocks of energy. This argument suggests that fusion is not a panacea and may bring more problems than it solves: thus, that no attempts should be made to develop fusion power unless it is quite certain that man will have the technical options and the political will to reject it if necessary.

## GEOTHERMAL POWER

60. Another possible energy source which could be considered consumption of capital rather than of energy

<sup>103</sup> Tritium and other light nuclei might be considered a trivial exception.

<sup>104</sup> The difference between theoretical and actual containment could be as important for fusion as for fission: fallibility and economic expedience could compromise safety analogously in both cases.

<sup>105</sup> This depends mainly upon how wide the choice of materials for the containment structures turns out to be. Alternatively, if extremely high temperatures can be attained, it may be possible to use certain fusion reactions which release no neutrons; this process would be far more difficult than the reactions currently contemplated, but would virtually eliminate activation products.

<sup>106</sup> Some would say that no nuclear source can be clean and safe; and that though nuclear power is admirable when properly sited, the source and user should be rather widely separated—say, about 150 million km.

income<sup>107</sup> is geothermal heat, now drawn only locally in the form of hot water and dry steam. Some research, of which there has been far too little, suggests that geothermal energy from hot dry rock, if obtainable, might be cheap and abundant enough to have a profound influence on world energy supplies. Side-effects are still speculative, but they could well be more acceptable than those of fossil fuels, despite low thermal efficiency. Little more can be said of this source<sup>108</sup> until further research is completed a few years hence.

#### SOURCES OF ENERGY INCOME

61. Having exhausted the known categories of energy capital usable in large amounts, the discussion now turns to possible technologies for exploiting energy income—energy flows which natural processes make continuously available, regardless of whether they are tapped. Such techniques, suitably deployed, are perfectly capable of providing as much energy as mankind could reasonably need.

##### *Tides*

62. Tides, the only such source not activated by the sun, can provide locally large blocks of physically clean (if ecologically disruptive) power from especially favourable sites, sometimes at competitive prices. For fundamental physical reasons, however, they cannot provide more than about a hundredth of the power potentially available from conventional hydroelectric stations. For this reason, and because of their special site requirements and relatively high capital cost, they are likely to remain of merely local interest.

##### *Hydroelectricity*

63. Hydroelectricity, the largest indirect source of solar energy currently used for generating power, could, in theory, be expanded more than 10 times to provide several times the total current world electrical capacity. Such full use will not be approached in practice because:

(a) The accumulation of silt renders most man-made reservoirs useless within a century or two (or even less); this problem may well be insoluble;

(b) As recent controversies have shown in the United States of America, where only about one fifth of theoretical capacity has been used, land-use conflicts can delay or prevent large hydroelectric developments;

<sup>107</sup> The uncertainty here is semantic, not technical. The outward flux of geothermal heat is continuous, but a power scheme would deplete local stocks of heat far faster than they are replenished, thus, in effect, consuming temporarily a slowly renewable capital stock.

<sup>108</sup> United States of America, Ninety-second Congress, Senate, Committee on Interior and Insular Affairs, *Summary Report of the Cornell Workshop on Energy and the Environment* (May 1972); R. W. Rex, "Geothermal energy, the neglected energy option", *Bulletin of the Atomic Scientists*, vol. 27, No. 8 (October 1971), pp. 52-56; United States of America, Ninety-second Congress, Senate, Committee on Interior and Insular Affairs, *Geothermal Resources and Research* (15 and 22 June 1972).

(c) Near-saturation or even over-saturation of prime sites in most industrialized countries means that the great bulk of unused theoretical capacity is in poorer countries which are unable to build their own dams and sometimes unable to obtain enough foreign help without onerous conditions. (Africa, South America and South-East Asia contain, respectively, 27, 20 and 16 per cent of the world's theoretical capacity);<sup>109</sup>

(d) Recent experience with large dams, especially in tropical countries, suggests that the geophysical, ecological, epidemiological and social side-effects of such massive projects may make them a very bad bargain. Smaller, more labour-intensive projects, and carefully integrated land-use planning, might significantly reduce such side-effects, but in the current state of knowledge it would be premature to reach wholly sanguine conclusions;

(e) Large water projects could have regional and even global climatic effects,<sup>110</sup> especially projects affecting the Arctic, e.g., diversion of Siberian rivers. Such effects cannot be accurately forecast with current knowledge, but are the cause of considerable concern. A combination of constraints (d) and (e) probably makes most major projects (e.g., Amazon, Mekong) inadvisable.

It appears unlikely that installed world hydroelectric capacity will double during this century. If it did, the increment would equal several per cent of current world energy conversion. The dependence of many developing countries on their hydroelectric resources, however, does make it very important for them that the above-mentioned problems be vigorously attacked.

##### *Indirect solar collection*

64. Solar energy can be collected indirectly by the following methods:

(a) Agriculture, forestry, fish-farming, hunting, fishing and gathering, all of which are beyond the scope of this paper;

(b) Synthetic agricultural systems designed to produce fuel by photosynthesis. This method looks less promising (for reasons of efficiency and ecological stability) than the use of natural productivity (general "biomass", or agricultural and human wastes) through direct combustion, distillation or fermentation. Like combustion of urban solid wastes, these techniques, currently used locally on a small scale, could be quickly developed as a useful supplement to conventional energy sources in many regions. Much more work is needed in this field;

(c) Windmills, which are of little use for centralized energy conversion, but can be very useful (where desired) in many rural areas. Their efficiency has greatly improved in recent years. The related problem of energy storage is briefly considered below;

<sup>109</sup> M. K. Hubbert, *loc. cit.*

<sup>110</sup> *Inadvertent Climate Modification, loc. cit.*

(d) Though harnessing of sea currents does not seem practicable, recent suggestions of operating heat engines from vertical temperature gradients in tropical oceans<sup>111</sup> may merit further study. Costs and side-effects are unknown; large-scale use in the next few decades seems rather unlikely. The technology could be explored through bottoming cycles in electricity generation.

#### *Direct solar collection*

65. The last possibility to be discussed is that of directly collecting the diffuse but enormous solar flux to generate high-temperature heat or electricity, for this is a major medium- and long-term option which, after decades of persistent but nominal effort, is just beginning to receive the attention it deserves.<sup>112</sup> (The recent Japanese commitment to major efforts in solar research and development is a straw in the wind.) Centralized conversion to electricity on a very large scale must, however, be distinguished<sup>113</sup> from diffuse conversion, e.g., in single-dwelling collectors that yield hot water and (through heat-pumps<sup>114</sup>) hot and cold air. The latter type of device is in use in many countries today, albeit in rudimentary form, and would probably be competitive with conventional methods in most temperate latitudes, if supported by modest development efforts. Indeed, there is good reason to believe<sup>115</sup> that diffuse solar technology may already be competitive with conventional methods anywhere in the United States or similar latitudes. There appears to be no fundamental reason why such domestic-utility technologies could not be widely proliferated within the next few decades, producing vast savings of fossil fuels. The barriers to this innovation appear to be entirely institutional. It is not generally realized that modern "selective black" surfaces—highly absorbent through the visible spectrum but poor radiators in the far infrared—can attain very high working temperatures, even on a cloudy day. After all, the effective working temperature of the sun as an energy source is about 5,500°K—nearly the boiling point of tungsten.

66. Centralized photothermal or photo-electric conversion is a somewhat peculiar concept, since one of sunlight's greatest virtues is free distribution. Major engineering studies<sup>116</sup> of large centralized systems are

<sup>111</sup> C. Zener, "Solar sea power", *Physics Today*, January 1973, pp. 48-53.

<sup>112</sup> A conservative round number for average insolation at temperate latitudes is 100 W per square metre.

<sup>113</sup> United States of America, House of Representatives, Committee on Science and Astronautics, *Solar Energy Research*, Staff report, Serial Z (December 1972).

<sup>114</sup> Properly engineered domestic heat-pumps would be very useful in any case.

<sup>115</sup> United States of America, House of Representatives, *Solar Energy Research*, *op. cit.*

<sup>116</sup> N. C. Ford and J. W. Kane, "Solar power", *Bulletin of the Atomic Scientists*, vol. 27, No. 8 (October 1971), pp. 27-31; A. B. Meinel and M. P. Meinel, "Is it time for a new look at solar energy?", *Bulletin of the Atomic Scientists*, vol. 27, No. 8 (October 1971), pp. 32-37; United States of America, Ninety-second Congress, House of Representatives, Committee on Science and Astronautics, *Briefings Before the Task Force on Energy*, by A. B. Meinel and M. P. Meinel, Serial U (6 March 1972), vol. III, pp. 32-52.

still embryonic, but suggest that capital costs are likely to be within striking range of current sources, if reduced by research and development the objective of which was to develop better materials.<sup>117</sup> Thin-film sandwiches and Fresnel-lens arrays look particularly interesting. Low maintenance cost, low environmental impact, free fuel and security of supply should weigh heavily against any residual increment of capital cost. It is argued that photothermal conversion requires a great deal of land, but, in fact, it requires less than prolonged strip-mining of coal and can coexist with certain other uses.

67. Solar power, in general, has several unique implications which do not arise from its obvious advantages (such as simplicity, guaranteed safety and feasibility, sufficient magnitude, free fuel and low environmental impact). For example, it could help to redress the severe energy imbalance between temperate and tropical zones; its diffuseness is a spur to decentralization and increased self-sufficiency of population (highly desirable on other grounds); as the least sophisticated major energy technology, it could greatly reduce world tensions resulting from uneven distribution of fuels and from limited transfer of technology; and by limiting the density and the absolute amount of power at man's disposal, it would also limit the amount of ecological mischief he could do, without necessarily limiting his ability to live a comfortable and happy life. Lastly, the climatic impact of a direct or indirect solar economy would be minimal.

68. Not all proposed solar-energy schemes are terrestrial: Glaser's proposal for large photo-electric collectors in synchronous orbit deserves mention. The economics of such a scheme are several orders of magnitude out of reach, though they may deserve re-examination several decades hence. The safety problems of transmitting the power to earth by means of focused microwave beams may be soluble. Possible military applications of such a microwave source may account for official interest in the scheme.

#### ENERGY SYSTEMS AND COMPONENTS

69. Completeness requires, but brevity does not permit, a detailed discussion of energy conversion, storage and distribution technologies, which may have more impact on energy supply than does the availability of primary fuels. A few short conclusions may give some of the flavour of recent work in this complex field:

(a) If approximately two thirds of the heat produced by primary fuel in the generation of electricity continues to be wasted, electrification should be strongly discouraged as inherently inefficient: indeed, most average efficiencies have fallen in the past few years. Correcting the scandalous waste of fairly high-temperature heat from power-stations, as with the district-heating schemes

<sup>117</sup> United States of America, House of Representatives, *Solar Energy Research*, *op. cit.*

common in Sweden, could reduce this objection gradually over the next few decades.<sup>118</sup> "Thermal pollution", in other words, could be put to good use, which would otherwise demand fresh primary energy. Meanwhile, the United States electric industry plans to use one half of primary energy in 2000 (now one fourth), which would require two thirds of the total continental runoff<sup>119</sup> as cooling-water to take the "waste" heat;

(b) Magneto-hydrodynamics (MHD) now looks less promising than combined-cycle gas turbines as a way of improving electrical generating efficiency. Early versions of the latter already are about as efficient as the best modern steam-raising plant and promise dramatic further improvement. Cryogenic generators and transmission lines also hold much in store;

(c) Electricity can be stored more flexibly, efficiently and cheaply in underground compressed-air reservoirs than by hydroelectric pumping—which is already uneconomic compared with peaking gas turbines. Battery technology continues to improve, but no real breakthrough is yet in sight. Electricity is still probably the most expensive form of energy to transport in bulk;

(d) Recent experiences of electrical utilities strongly suggest that the economies of scale alleged for large central stations and components may be illusory. Not only is component reliability subject to important diseconomies of scale, but the whole subject of centralized *versus* diffuse energy conversion needs fundamental restudy;

(e) Heat storage is not as difficult as is often supposed, especially on a small scale. Large-scale schemes for underground storage of hot water<sup>120</sup> may be a relatively easy answer and deserve study;

(f) Chemical energy storage—as refined petroleum products, natural gas in gaseous or liquid form, hydrogen, alcohols etc.—is an immensely intricate subject linked with, e.g., transport engineering, fuel-cell technology and industrial chemistry. Research can probably make it possible to assess on paper the implications of the theoretically elegant and flexible hydrogen economy<sup>121</sup> and of the possible advantages of a safer, probably cheaper and more easily adopted methanol economy.<sup>122</sup> Methanol is already cheaper in long-haul

transport than LNG<sup>123</sup> and offers both a smooth route of transition from an oil to a hydrogen economy and a convenient way of storing hydrogen in, e.g., vehicles—a carbon and an oxygen atom serve, in effect, as carriers for four hydrogen atoms;

(g) Microbiological and enzymatic methods of energy conversion, ranging from the Calvin/Tributsch photo-electric cell to astonishingly efficient methods of producing hydrogen and methanol from simple substrates and then reconvertng these fuels into biological fuel cells, may produce many surprises in the coming decade.<sup>124</sup>

70. Obviously, no "unconventional" energy technology, or combination of technologies, offers an instant panacea; and the utility of particular choices will depend upon local needs, which vary as widely as the range of fossil-fuel options. One can, however, argue that any strategy of research and development should favour as diverse as possible a range of options. Needs change, technological adventures fail and plans need constant revision; but in diversity lies safety. The possible virtues of decentralized energy conversion need special stress: they may include lower cost, greater flexibility, smaller strategic vulnerability, higher system efficiency, lower risk, greater resistance to monopoly, compatibility with a wider range of human settlement patterns and (depending upon the technology considered) greater self-sufficiency in a world of increasing interdependence and instability. Energy independence is already becoming a major objective of public policy in those countries where indigenous resources (ranging from coal to low latitude) permit it, and current political events will surely speed the trend.

#### ENERGY CONSERVATION

71. Most of this paper has been concerned with what an economist would call "energy sources" rather than "energy uses". While trying to redress this imbalance in the short space remaining, one must not make the common error of supposing that "energy demand" is any less important than "energy supply". In the next few years, it will be learnt that however much energy people "demand", they cannot use it if it is not available. From now on the choice will rapidly become clearer: whether to reconcile demand with need, according to an orderly plan; or by panicky improvisation in the face of imminent shortages. The countries most responsible for these shortages can reflect that were their people not using several times as much energy as they need, cheap energy supplies could be available to the rest of the world for some decades to come. If energy use *per capita* in the United States of America were reduced to that of, say, France, the amount

undated); J. C. Davis, "Can methanol fuel contend?", *Chemical Engineering*, 25 June 1973, pp. 48-50.

<sup>123</sup> B. Dutkiewicz, "Methanol competitive with LNG on long haul", *Oil and Gas Journal*, 30 April 1973, pp. 166-178.

<sup>124</sup> C.-G. Hedén, Karolinska Institute, Stockholm, has surveyed such options.

<sup>118</sup> The importance of using "waste" heat for heating or industrial processes can hardly be overemphasized. The obstacles are less technical or economic than institutional. To overcome these obstacles, it may sometimes be worth while to degrade high-temperature heat deliberately, in order to insert a stage of buffering between the power-station and the users.

<sup>119</sup> S. F. Singer, "Environmental quality and the economics of cooling", in D. A. Berkowitz and A. M. Squires, *op. cit.*

<sup>120</sup> C. F. Meyer and D. K. Todd, "Conserving energy with heat storage cells", *Environmental Science Technology*, vol. 7 (June 1973), p. 512-516.

<sup>121</sup> Several recent informal studies suggest that a hydrogen economy, properly designed, need not be unduly hazardous. More work is needed.

<sup>122</sup> T. B. Reed, "The methanol economy—a practical version of the hydrogen economy", Massachusetts Institute of Technology, Lincoln Laboratory, internal report (Lexington, Mass.,

"saved" would suffice to give everyone else in the world nearly a fourth more energy than he now has.

72. A few simple examples, easily multiplied, will illustrate the scope for energy conservation in the industrialized countries:

(a) Most modern architecture is extremely energy-intensive, with absurdly high lighting levels, poor insulation, universal air-conditioning, electric heating, excessive volume, excessive use of such energy-intensive materials as cement and aluminium, and non-solar orientation. The modern attitude in this sector is perhaps best exemplified by the World Trade Center in New York, a single building wired for 80 MW; by office buildings where neither air-conditioners nor lights can be turned off (though if it gets too cold one can turn on the electric heater as well); by the way cities are heated with power-stations to run air-conditioners that make the cities hotter; and by the apparent inability of the Government of the United Kingdom (among others) to prescribe for houses the minimal standard of roof insulation required for piggeries (though heavier insulation still, as is common in Scandinavia, would pay for itself in a year or two and would be, perhaps, the most cost-effective way of helping the balance of payments of the United Kingdom);

(b) The extravagance of modern private transport and the poor deployment of public transport are too obvious to need much comment. Transport accounts directly for about 25 per cent of total energy conversion in the United States, almost twice as much as for space heating and cooling (transport in the United Kingdom is only a slightly smaller fraction). Institutional reforms are badly needed in such areas as motor-car insurance regulations and airline franchising (e.g., perhaps commercial aircraft could be shared in a common pool, just as railway freight-haulers in the United States share their rolling-stock). Using canals, and even such unconventional methods as containerized airships, could be worth while for intercity freight transport. Better communication, too, could help to move information rather than people, at far lower energy cost;

(c) The energy cost of non-recycled materials (about one seventh of the energy in the United States) and of intensive agriculture (especially in the use of protein feed-stocks) is unknown, but undoubtedly sensational. The direct energy cost<sup>125</sup> of 1 kg of protein in English milk is estimated to be equivalent to about 20 litres of petrol. Slessor<sup>126</sup> cites a Stanford Research Institute estimate that in the United States modern production of 1 kg of beef protein requires about 350 MJ, equivalent to about 12 kg of coal;

(d) Energy is substituted for political and moral, as well as for physical, resources. Preparations for war (the ultimate form of conspicuous consumption) account for several per cent of world energy conversion. The

potential energy represented by current stockpiles of nuclear weapons would, were it food, feed everyone on earth for a decade. The potential energy represented by munitions detonated by the United States over South-East Asia in 1965-1971 is equivalent to the food input of some 2 million people over the same period.

Energy waste cannot be avoided nor rational energy policies devised unless the energy costs of each technology and of each material flow are known. The development of value-added energy accountancy is just beginning,<sup>127</sup> albeit in a haphazard and unco-ordinated form. Better information on where the enormous energy conversion goes and what is obtained for it, presented in sufficient detail that it will be possible to energy-budget, for example, fresh peas *versus* frozen peas, is likely to produce many surprises. It will encourage the evolution of a whole-systems approach that uses integrated design to match various forms of energy to the most appropriate uses and to minimize total conversion. This method is likely to be cheapest in the long run and to minimize ecological damage.

73. In this connexion, the intimate relationship of energy strategy to practically every other major area of policy must be stressed once more. The energy-intensiveness of modern agriculture has already been mentioned. Still more complex is the role of energy in human settlements. Modern urban agglomerations may have a power density so high, and so vulnerably expressed, as to be unsustainable in an era of limited and uncertain energy supplies. Plans for urbanization must take this into account.

#### Forecasting

74. Energy forecasting, currently in considerable ferment, needs to be rebuilt around causality rather than correlation, so that the validity of assumptions and the state of fundamental determinants of energy demand can be constantly reviewed. It is not yet known what these determinants are, nor what the price elasticity of demand might be for any particular form of energy, nor whether large price rises would have much effect on industrial economies as a whole (as opposed to, e.g., the private transport sector; fuel costs in the former have in the past been a small fraction of total costs). A mature science of energy forecasting would also include an institution to anticipate and identify, and to assess the energetic consequences of, changes in technology or in market patterns.<sup>128</sup> Rational regulation of undesirable trends is impossible unless potentially energy-intensive products or practices can be noticed early, before decision-making becomes politically painful.

<sup>127</sup> It is not even known yet whether nuclear-fission technology, taking all inputs into account, is likely to be a net producer of energy.

<sup>128</sup> The "full-steam-ahead" scenario of the Ford Energy Policy Project has had to assume a modest saturation in energy demand in the United States of America by 2000: not because supply constraints were assumed, but because the Project staff could not devise plausible ways to use that much energy.

<sup>125</sup> G. Leach, personal communication.

<sup>126</sup> M. Slessor, "Energy analysis in policy making", *New Scientist*, vol. 60 (November 1973), pp. 328-330.

### *Doing more with less*

75. Though there is a great deal to be learnt about the social role and the physical function of energy in various societies, enough is now known to be confident that energy demand in most highly industrialized countries is several times their actual need. Action must be taken promptly to put this knowledge into practice. In the United States of America, for example, a politically acceptable strategy could be devised and implemented within two years for an orderly reduction of the energy growth rate by perhaps 0.3-0.5 percentage points per annum, reaching zero within about a decade, despite continuing population growth. The author believes that without prohibitive cost or disruption, the level of energy conversion in the United States could then be smoothly reduced,<sup>129</sup> at a rate of, perhaps, 1-2 per cent per annum, by a factor of at least two over the ensuing two or three decades—again despite continuing population growth. It is unlikely that anyone who has seriously studied the scope for energy conservation and redeployment of economic activity in the United States will quarrel with this conclusion.<sup>130</sup> Similar, though perhaps less drastic, economies are undoubtedly possible throughout the industrialized world and are often necessary on other grounds (e.g., food supply). No world or national energy strategy can succeed without close attention to such measures.

76. In order to devise strategies for the orderly reduction of energy use *per capita* in the more industrially developed countries, one will need not only value-added energy accounts for goods and services, but, as a basis for policy decisions, detailed scenarios of alternative life-styles at varying levels of energy intensity. Also needed will be detailed assessments of the social, ethical, political and humanistic implications of technical and strategic choices—more important, perhaps, to consider now than the technical and economic implications, which, though important, do not deserve to monopolize the attention of decision-makers. It will take many years of assiduous effort to develop all these tools; mankind cannot wait that long. But though one does not yet know exactly what to do, one has a good

<sup>129</sup> As simple calculations show, merely slowing the energy growth rate buys very little time (see C. L. Wilson, *loc. cit.*). To make the problem soluble, the rate of change of energy conversion must be swung slightly negative. Of course, reductions in *per capita* energy conversion could be "sold" to the public, not as cuts in the level of living, but as improvements in the quality of life.

<sup>130</sup> Recent studies by the North Atlantic Treaty Organization and the United States Office of Emergency Preparedness envisage possible energy savings of the order of one seventh to one fifth by the early 1980s. These rather conservative figures—which, incidentally, amount to a negative growth rate of several per cent per year—would be far larger if extended over a long-enough period to reflect substantial changes in life-styles, rather than merely cosmetic changes, or if one had the tools (value-added energy accounts and clearly stated alternative sets of social norms and goals) with which to do a more sophisticated and detailed calculation of possible savings. Nobody has yet addressed such interesting questions as the energy budget of, say, the United States of America with a material standard similar to that of 1910, but with modern medicine, communications and similar amenities.

idea of what not to do, and there is no need to wait for every last fact to come in before one stops doing it. Large public projects centred round the private motor-car offer an excellent example of resources that deserve a better fate.

### ENERGY ISSUES

77. So far, this paper has tried to give an overview more of the facts than of the issues in world energy. It is time now to review and stress some important issues that must affect the choice of energy strategies.

#### *Distribution*

78. First to be considered is the drastically skewed distribution of energy resources and of energy consumption. Correcting the latter problem will require far more responsive and far-seeing management in the industrialized countries, ready to formulate deliberate strategies for energy conservation<sup>131</sup> before rationing and failures of supply enforce a haphazard and spartan self-sufficiency. It will also require societies with quite different goals to learn from the mistakes into which an expanding economy of flow has led their materially richer, though not always happier, neighbours. Furthermore, skewed energy distributions not only in space but in time, as subsidies are stolen from the future,<sup>132</sup> raise issues fundamental to the morality of modern industrial societies.<sup>133</sup>

#### *Risk*

79. Next is the equally important issue of risk. Rapid growth in energy conversion increases the magnitude and likelihood of mistakes. It also appears recently to have come to depend upon the rapid development and deployment of technologies so complex and so novel that their side-effects may be unpredictable—or, more commonly, may be predicted but not taken properly into account in decision-making, owing to institutional momentum or to the distractions of a crisis atmosphere.

80. It is instructive to study three outstanding examples of exceptional, and little-known, risks in new energy technologies:

(a) Unirradiated or reprocessed fissile isotopes, with half-lives of 10,000 years or more, must be perpetually safeguarded against "diversion" (theft) by terrorist groups, non-nuclear Governments, lunatics, criminal syndicates or speculators. A few kilogrammes of <sup>233</sup>U, <sup>239</sup>Pu or highly enriched <sup>235</sup>U—regardless of chemical

<sup>131</sup> H. Perry, *op. cit.*

<sup>132</sup> As Hugh Nash remarks, what better way is there to show our faith in our descendants' boundless technological ingenuity than to make sure they need it?

<sup>133</sup> The problem of a sustainable energy economy is inseparable from that of a sustainable economy—an economy of stock in which growth is no longer used as a substitute for distribution (the "let-them-eat-growth" principle) and in which moral growth is combined with a biophysical steady state. H. E. Daly, *Toward a Steady-State Economy* (San Francisco, Calif., W. H. Freeman, 1973).

form—can be made into a crude, but wholly convincing nuclear weapon<sup>134</sup> by a physicist with a small group of dedicated technicians, a £10,000 model shop, less than a year and techniques thoroughly described in the open literature,<sup>135</sup> mainly in publications issued by principal public nuclear agencies and thus likely to be considered authoritative. Experience in fabricating strategic materials is available from thousands of people now in civilian life, but is not essential. Indeed, actual manufacture of a weapon is optional if a credible threat of having done so can be manufactured instead.<sup>136</sup> Reactor-grade, rather than weapons-grade, plutonium is suited for sophisticated amateur weapon-makers if an unpredictable, but large, yield is sufficient.<sup>137</sup> Recycling of <sup>239</sup>Pu will extend safeguards problems to most thermal reactors: a 1-GW (e) light-water reactor makes several hundred kilogrammes of <sup>239</sup>Pu a year. Highly enriched uranium fuel, however, such as that of high-temperature gas-cooled reactors, is easier to fabricate, though less reactive. A home-made weapon which failed to achieve instant criticality and high yield could still do immense damage—and, in disassembling, disseminate <sup>239</sup>Pu and the like. Extensive, mainly secret, and certainly inadequate, measures are now taken to prevent theft of strategic material. The safeguards systems literature shows that continual small thefts from fuel facilities are, in principle, undetectable; that it may take weeks or months to detect large single thefts; and that the precision of inventory assay, though improving, is likely to remain inadequate to detect small sporadic thefts. Moreover, since safeguards techniques concentrate on where strategic material is supposed to be, rather than on where it is not supposed to be, it is hard to tell where stolen material has gone. Recovery presents extreme difficulties, especially after a theft from the vulnerable transport network<sup>138</sup> (tens or hundreds of shipments daily in a mature <sup>239</sup>Pu economy). Safeguards more costly and thorough than those now applied to fissile isotopes have failed to halt aircraft hijackings, bank robberies and the

<sup>134</sup> The suitability of an isotope for weapons depends on, *inter alia*, the ratio of its fast-neutron fission cross-section to its non-fission capture cross-section. This ratio is rather favourable for some isotopes which are not fissile in the usual sense, *viz.* fissionable by slow neutrons. Study of the published cross-sections at the appropriate energies shows that a fast critical assembly can be made from reasonable quantities of certain isotopes which are not fissile, and some of which are not now safeguarded. The present discussion therefore refers to "strategic material", not just to the three fissile isotopes named or to "special nuclear material" as defined by regulations of the United States Atomic Energy Commission.

<sup>135</sup> D. P. Geesaman, "Plutonium diversion", presented at the California Legislature's Assembly Science and Technology Council's Energy Panel on Radiological Issues Related to Nuclear Power Plants, 15 June 1972.

<sup>136</sup> R. E. Lapp, "The ultimate blackmail", *New York Times Magazine*, 4 February 1973.

<sup>137</sup> V. Gilinsky, "Bombs and electricity", *Environment*, vol. 14, No. 7 (September 1972), pp. 10-17.

<sup>138</sup> The recent decision of the United States Atomic Energy Commission that substantial shipments will be accompanied by armed guards will presumably make shipments more conspicuous. It is doubtful that such measures will deter any but the casually curious.

black market in heroin (whose black-market price is comparable to the open-market price of <sup>239</sup>Pu; nobody knows, one hopes, what <sup>239</sup>Pu might cost in a demand-stimulated black market). Such analogies suggest, and the technical literature tends to confirm, that it is impossible to prevent the theft of strategic material by sufficiently determined groups whose motives "are subversive or economic";<sup>139</sup>

(b) The marine carriage of liquefied natural gas (LNG) is now in its infancy, but has a current doubling-time of under two years.<sup>140</sup> Receiving terminals for large and highly sophisticated LNG tankers are planned or are being built in urban and semi-urban harbours.<sup>141</sup> LNG is essentially liquid methane (CH<sub>4</sub>), carried at about -165°C. If spilled on water, it boils extremely quickly, forming a cloud of methane gas which, by reason of its extreme cold, is denser than air and forms a ground-level cloud or plume. Such a plume—which might, in the case of a large tanker spill, extend at least 5 km downwind within 10-20 minutes<sup>142</sup>—is asphyxiating. It is readily ignitable, and will burn to completion in a turbulent diffusion flame reminiscent of the Hindenberg disaster in 1937 (but 100 times as large). Spillage of LNG after a collision or hard grounding (or, conceivably, after sabotage of a tanker or terminal) would be promoted by brittle fracture<sup>143</sup> of metal structures, such as hulls, on impact of the cryogenic cargo; experience of such incidents suggests that plate failure could propagate and cause an LNG carrier to unzip like a banana. The energy content of a single LNG carrier of 125,000 m<sup>3</sup> (the standard size now being built) is equivalent to approximately 55 Hiroshima bombs;

(c) A recent paper<sup>144</sup> plausibly suggests that a large spill of oil in the Beaufort Sea is physically capable of reducing the albedo (reflectivity) of large areas of the Arctic pack ice. The oil could emulsify into small,

<sup>139</sup> The masterly survey of the safeguards problem compiled by Taylor and Willrich for the Ford Energy Policy Project (January 1974) is strongly recommended. Its logic leads one to surmise that the steps for transition to a fission-free economy should include consumption of all transuranic stocks in low power density, remotely sited and diligently guarded reactors. See also D. P. Geesaman, *loc. cit.*

<sup>140</sup> E. Faridany, "LNG marine operations and market prospects for liquefied natural gas 1972-1990", QER special No. 12, Economist Intelligence Unit, London, 1972.

<sup>141</sup> J. A. Fay and J. J. MacKenzie, "Cold cargo", *Environment*, vol. 14, No. 9 (November 1972), pp. 21-22.

<sup>142</sup> Lt. Cmdr. H. D. Williams, *Proceedings of the Marine Safety Council*, vol. 28, No. 9 (September 1971), p. 162; see also vol. 29, No. 10 (October 1972), p. 203. The similar estimates given by J. A. Fay and J. J. MacKenzie, *loc. cit.*, have a somewhat firmer theoretical base and are undoubtedly conservative. Naturally, nobody has yet tried a full-scale experiment.

J. C. Dobson, "Problems in the design and construction of liquefied gas carriers", paper 7, LNG/LPG Conference, London, 21-22 March 1972, *Shipbuilding and Shipping Record*.

<sup>144</sup> W. J. Campbell and S. Martin, "Oil and ice in the Arctic Ocean: possible large-scale interactions", *Science*, vol. 181 (6 July 1973), pp. 56-58.

highly persistent droplets which, circulated in the currents, would collect on the underside of the pack ice. Seasonal melting on top and freezing on the bottom would then yield a darkened ice surface in a few years. It is known<sup>145</sup> that the Arctic pack ice is in an extremely delicate state and could be quickly melted by certain types of small perturbations, with profound and irreversible effects on world climate. A small reduction in ice albedo, especially during April and May, could promote melting very effectively.<sup>146</sup>

81. Risks of this magnitude—all uninsured and uninsurable—clearly deserve a more earnest public debate than they have received. Risk (a) is the subject of intense professional worry and vague public unease; risk (b) has stimulated a small, comparatively obscure literature and a tendency for the responsible agencies to look the other way;<sup>147</sup> and risk (c) is virtually unknown except to a handful of climatologists, who are taking it very seriously. It is worth noting further that all three of these risks are acute, not chronic: nobody knows the cumulative long-term effects of modern energy technologies on, e.g., human health, genetic resources or the stability of ecosystems. Interference with natural energy flows by means of intensive agriculture offers a particularly worrying example. Indeed, it is hard to think of any current energy technology in extensive use that does not hold the potential for serious long-term environmental risks—risks which today may be wholly unsuspected.

#### *Ethics*

82. The strong ethical ingredient of future-risk problems is perhaps most clearly seen in the perennial controversy, apparently as far from resolution as ever, over the rather arbitrary standards for human exposure to ionizing radiation. Critics of these standards argue, rightly, that safety has not been proved. Advocates reply, correctly, but perhaps immorally, that harm has not been proved. Critics point to disquieting statistical trends—inconclusive but suggestive—and say that the burden of proof should rest on the innovator, as is theoretically the case with even the most beneficial drugs. Advocates can take comfort in the difficulty of demonstrating any real low-level effects, because of the lack of controls in large populations and the lack of statistical significance of small long-term effects in small populations. Meanwhile, while several thousand million people are being asked to sign by proxy an irrevocable Faustian bargain,<sup>148</sup> whose small print they have not read and are told they cannot understand, those perhaps most affected—thousands of generations yet unborn—

<sup>145</sup> *Inadvertent Climate Modification, op. cit.*

<sup>146</sup> *Proceedings of the Twenty-Fourth Alaskan Scientific Conference, Fairbanks, 15-17 August 1973, passim.*

<sup>147</sup> Some agencies, however, are worried. Loadings of liquefied natural gas (LNG) may prove hard to license, and some major groups of insurance underwriters are also becoming wary of large LNG tankers and terminals.

<sup>148</sup> A. M. Weinberg, "Social institutions and nuclear energy", *loc. cit.*

are not consulted at all. As Kneese stresses,<sup>149</sup> this sort of ethical issue is beyond technical scope or competence, is too important to be left to experts and requires instead to be resolved explicitly in the most open forums of society. This procedure will be slow and hard, but it is scarcely a dispensable luxury.

#### *Conflict*

83. Issues as complex, but of a mixed ethical and pragmatic character, are raised by the enormous conflict potential of inequities in the distribution of world fuel resources. The inherent delicacy of politics in the Middle East, the likelihood of massive armaments purchases there, the prospect of increased energy competition between the United States and other countries of the Organisation for Economic Co-operation and Development (OECD) and the growing importance of such commodities as gas from Siberia, tar-sands from Canada and enriched uranium from the United States need no emphasis. The divergent interests now tugging at physical resources, too, will become more and more concerned with intangible resources, with technology, as the countries best able to afford difficult research monopolize the results to their own advantage and ignore or exploit the technological dependence of others. Such advances as would most benefit the poorer countries, however, they will probably have to make for themselves as best they can, since the technically advanced countries are, for the most part, too busy with their own problems to consider the workings of an energy-conserving, labour-intensive, decentralized society.

#### *Outer limits*

84. Lastly, the ultimate constraints—local, regional and global—on human energy conversion raise important medium- and long-term issues that would defy resolution by existing institutions. Not considered here are the possible outer limits that have yet to be even roughly quantified, for example, those imposed by the availability of land or of capital (about £5 × 10<sup>11</sup>, perhaps £ 10<sup>12</sup>, needed for the world oil industry alone by the mid-1980s) or by the biological implications of much by-products as transuranic isotopes or sulphur compounds. The discussion here is concentrated upon climatic limits, where the current state of knowledge is as follows.

85. Man-made particulates, some from combustion, already form a substantial fraction of the atmospheric load. Combustion (except of hydrogen) also causes an upward trend, averaging 0.2 per cent per annum in the atmospheric concentration of carbon dioxide. These two effects are, in some respects, competitive in their effects on global climate, but may, in other, and perhaps more important, respects be co-operative, tending to reinforce the effects of man-made heat. They may become important in the first half of the next century. Some

<sup>149</sup> A. V. Kneese, *loc. cit.*

scientists<sup>150</sup> suspect they may already be significant on a regional scale.

86. The influence of man-made heat—the end-product<sup>151</sup> of any energy conversion, regardless of the technology used—is already great locally and will, soon, become significant regionally. Most large industrial areas, including several with areas of about  $10^{10}$  m<sup>2</sup>, already add on the order of 10 per cent of net solar heat input to the surface; such areas are projected to intensify, multiply, spread and merge. The distribution of such regional “heat islands” will be very uneven and mainly at high northern latitudes. The man-made power density of Manhattan Island in New York City (over 700 W per square metre from man, compared with 93 net from the sun) is very exceptional,<sup>152</sup> but perhaps illustrates what can be done.

87. Global climate is capable of rapid transitions between very different states. These transitions can be triggered by relatively small perturbations applied at particularly sensitive leverage points, such as the floating Arctic pack ice.<sup>153</sup> Man-made heat might well be able to provide such a perturbation, at current growth rates, in the first half of the next century, and could certainly do so shortly thereafter.<sup>154</sup> An immense amount of intricate research must be done to determine when such a threat might arise, since it must not be studied empirically. Such research might not yield a definite answer. Though from current, very limited, knowledge it appears that the current pattern of energy growth is probably safe for a few more decades, alternative long-term strategies not involving energy-intensive technologies must be developed promptly in case, as is plausible, global thermal limits make it inadvisable to seek an energy increase of factors of 10. Any long-range commitment now to an order-of-magnitude energy increase is definitely premature.<sup>155</sup>

88. Regional climate is capable of periods of prolonged aberration from the mean, such as repeated seasons of drought or storm. Such fluctuations have profound effects on social and economic systems, especially in the current precarious state of world food supplies. There is as yet no firm evidence to implicate in, or to exonerate from, regional climatic disturbances possible man-made perturbations.<sup>156</sup> Urgent research

into this question, and into the influence of climatic change on man's activities, is now beginning.

89. The many unresolved questions about basic climatic mechanisms make present rapid energy growth-rates disquieting and suggest to many climatologists that a policy of caution should be adopted without delay. These doubts imply, also, that world energy problems cannot be realistically treated as a sum of national problems in a strongly interactive and non-linear world. International institutions able to regulate man's influence on climate may become essential soon, especially in view of major water and deforestation proposals currently under study.

## CONCLUSIONS

90. This paper has only scratched the surface of a body of problems whose detailed exposition would be the work of many lifetimes; yet even at this level of detail, the information density has been so high that it would be quite wrong to attempt a summary. It may be useful to present, instead, certain inferences which the author believes could properly be drawn from the foregoing assessments. To sharpen the focus, the number of such conclusions has been arbitrarily limited to 10:

(1) The rapid energy growth-rates that most industrial countries have long maintained cannot continue for much longer. Governments should adjust to this reality and devise long-range strategies consistent with it, and with the other resource constraints that it entails. Even the ability to maintain current levels of energy conversion *per capita* in many more industrially developed countries over the next few decades is in doubt;

(2) Industrial countries should immediately undertake lasting and fundamental (not temporary and cosmetic) measures to conserve energy in all sectors and forms, and particularly to minimize the consumption of oil and natural gas. The methods that have so effectively promoted these forms of consumption must now be put into reverse;

(3) Means of minimizing the social and environmental costs of mining and burning coal are urgently needed, as coal and its synthetic products offer many countries their only short- and medium-term bridge from a petroleum economy to a sustainable energy economy. The problems of coal are substantial but can be solved;<sup>157</sup>

(4) A diverse range of “unconventional” energy technologies, especially those based on energy income rather than on energy capital, should be developed and deployed as quickly as possible, with the help of suitable incentives. Both new and current energy technologies should be integrated into systems that use each form of energy as appropriately and efficiently as possible;

<sup>157</sup> One might make a reservation about the sub-micron particle problem (see foot-note 46); but presumably that can be evaded through coal conversion to synthetics.

<sup>150</sup> R. A. Bryson, “Drought in Sahel: who or what is to blame?”, *Ecologist*, vol. 3, No. 10 (October 1973), pp. 366-371.

<sup>151</sup> The reference here is not to local “thermal pollution”—the discharge, often ecologically important, of “waste” heat from a power cycle—but to the requirement of the second law of thermodynamics, that all energy end as low-temperature heat, no matter for what purpose or by what means it is converted.

<sup>153</sup> *Ibid.*

<sup>154</sup> See the two articles by A. B. Lovins, “World energy strategies”, *Bulletin of the Atomic Scientists*, vol. 30, No. 5 (May 1974), pp. 14-32; and, “World energy strategies, part 2: the case for long-term planning”, *Bulletin of the Atomic Scientists*, vol. 30, No. 6 (June 1974), pp. 38-50.

<sup>155</sup> *Ibid.*

<sup>156</sup> R. A. Bryson, *loc. cit.*

(5) The fiscal and human resources now devoted to nuclear fission programmes, and particularly to fast-breeder reactor development, should be directed forthwith to aims (2)–(4). Governments should suspend their nuclear programmes until enough infallible people can be found to operate them for the next few hundred thousand years;<sup>158</sup>

(6) All oil and gas resources should be carefully husbanded—i.e., extracted as late and as slowly as possible. The descendants of this generation will be grateful;

(7) Governments and their constituencies in the highly industrialized countries should begin to contemplate seriously and to decide upon the changes in life-styles that energy and other constraints will soon impose—changes that may well be desirable on other grounds;<sup>159</sup>

(8) The energy technologies most appropriate to the poorer countries are also likely to be those on which the richer countries will mainly rely in the long run. These technologies should therefore be developed and transferred (with careful attention to the corresponding need for social and institutional transfer, which may have undesirable side-effects) as soon as possible, even though that may mean advancing the development schedule that the rich countries' own needs would dictate. World trade patterns should then be realigned to take account of the redistribution of energy. Interim means should be urgently sought to assist those developing countries whose importation of energy-intensive technologies (especially in agriculture) has made them dependent upon energy which, due to others' extravagance, they can no longer afford;

(9) Countries not yet industrialized should make every effort to avoid others' mistakes by (in general) minimizing their populations, maximizing their agricultural self-sufficiency (particularly in the use of sustainable, labour-intensive methods) and minimizing their need for large amounts of industrial energy. The rapid introduction of diffuse and medium-scale solar power should help, especially in tropical countries, to reduce urbanization by improving rural economies and living conditions. It is impossible to bring world energy conversion *per capita* up to the levels of rich countries;

<sup>158</sup> It may be argued that man cannot do without fission, but: (a) man is in effect doing without it now; (b) there are at least two long-lived major technologies—coal and solar technologies—that are known will work and that have no problems remotely comparable to the safety, waste and safeguards problems of fission; and (c) if man really cannot do without fission, then—assuming the current engineering problems with it to be overcome—all long-term planning becomes academic.

<sup>159</sup> Many, perhaps most, of these changes could be for the better. None the less, very careful planning will be needed to minimize discontinuities. The transition to a sustainable energy economy has much in common with a transition to a macro-stable, micro-variable economy of stock that prefers services to material consumption. In both cases, stabilization or reduction of population size and local self-sufficiency in food production must be top priorities. (See H. E. Daly, *op. cit.*)

on the contrary, the latter levels should be considerably reduced as an essential part of redistribution;

(10) All countries should take note of the following points of policy:

(a) Economic processes are often assumed to have limited materials inputs, unlimited energy inputs and market-limited outputs. Boundary conditions on the energy inputs are now needed.<sup>160</sup> In short, physical law imposes limits on technology; and physical, as well as economic, factors must govern energy;

(b) A science of energy impact analysis must be devised so that energy can be made a critical variable in all policy decisions, rather than leaving it to emerge *de facto* from decisions taken on other grounds;

(c) Need must be distinguished from demand and needless demand must be curbed. Rates of energy growth must be reduced or reversed in industrial societies before it is done for those societies by the consequences of current rapid growth;<sup>161</sup>

(d) In order to make rational long-term decisions, longer than about 20 years,<sup>162</sup> man must learn about the non-linear behaviour of biological systems, rely less on discounted cash-flow planning, stop discounting future risks, greatly lengthen man's time horizons, rely on economic sensitivity analysis rather than on marginal-cost analysis and anticipate socio-technical lags by sophisticated and diverse strategies of research and development. Slower, or negative, energy growth, properly used, can buy the time needed to do these things;

(e) Man must adopt explicitly the methodology of decision-making under uncertainty, recognizing that even events of extremely low probability may occur and must be guarded against;

(f) Lastly, one must keep more clearly in mind the ways in which the time-scale selected for planning can effect the choice of strategies. Pursuing a short-term goal (such as independence from imported oil) can foreclose long-term options, just as some countries are restricted now by short-term planning in the past. Planning is a process of formal procrastination, and its aim in an uncertain world must be to keep as many options open as possible. Current energy policies, however tacit and ill-constructed they may be, are quickly destroying the options that mankind, living and unborn, will need for millennia.

<sup>160</sup> This is so if only because the capacity of a given volume of space-time safely to accept heat is a strictly non-renewable and non-substitutable resource (a concept foreign to most economists).

<sup>161</sup> A system with rapid rates of change compared with built-in delays is inherently unstable. The instability can be reduced by reducing the rates of change; or by reducing those delays that are due to social rather than to natural causes (for example, by autocracy); or by accurate long-range predictive planning methods that do not now exist. The world appears to a system in this state.

<sup>162</sup> As Maurice Strong points out, currently used discount rates imply that the current value of a child is essentially zero.

## ENVIRONMENTAL PROBLEMS OF THE DEVELOPED COUNTRIES \*

*Joseph L. Fisher* \*\*

1. Environmental problems have been increasing in severity quite rapidly in most parts of the world, especially in the more developed countries and regions. Air pollution in cities has mounted as more and more people have crowded in looking for employment. Water pollution, again especially in urban regions, has increased with the growth of industry as well as of population. Congestion has become worse in housing and on streets. Noise has become more bothersome as the numbers of motor vehicles, industrial operations and building construction have increased. The disposal of solid waste from industrial, commercial and household sources has become a major concern of city managers and administrators. A few pollutants, such as certain chemicals and toxic metals, and, of course, radio-active materials, have tended to spread widely through the atmospheric and ocean systems of the world, while general increases in heat discharges and carbon dioxide may be exerting slight though profound effects on hemispheric climate. Individual and social amenities associated with a clean, uncluttered and orderly environment have been lost. Wilderness and wildlife have been endangered. Parks and open spaces in cities are inadequate to meet needs. Land planning, river-basin planning, air-shed planning—environmental planning in general—have been inadequate. Most of these conditions arose earlier in the more developed countries than in the less developed ones, and came on faster.<sup>1</sup>

2. Environmental problems can be classified in various ways: by type of pollutant; by cause or source of the problems, such as population growth, industrialization, behaviour of consumers or mode of technology; by effects on health, income or social welfare; by geographical areas; and by policies or measures for dealing with the problems. The purpose one has in mind should govern the classification system chosen. In this paper environmental problems are described under conventional headings of air, water, land, congestion, amenities and toxic materials. The more developed countries exhibit all these types of pollution in relatively

high degree. Following this brief description, the major demographic, economic, technological, social and behavioural sources of environmental disruption are delineated, and the principal consequences are then characterized in terms of economic, health, social welfare, and amenity and aesthetic factors. Because environmental conditions vary greatly within developed countries, as well as among them, some attention is given to regional differences which now exist and, no doubt, will continue to exist. Lastly, alternative policies and programmes of action designed to deal with the problems are considered. Some of these are national in scope, some intra-national and some international. Special issues arising between the more and the less developed countries also are considered.

### ENVIRONMENTAL PROBLEMS OF AIR, WATER AND LAND

3. In most respects, air quality in the urban regions of developed countries has been deteriorating for a long time, certainly since the onset of industrialization. Both ancient and mediaeval cities stank because of primitive sewerage facilities, but air pollution in the modern sense hardly existed. The so-called "industrial revolution", beginning in the late eighteenth century in England and then spreading to western Europe and north-eastern United States of America, was fuelled primarily by soft coal, which was burnt inefficiently yielding much soot and sulphur, and other compounds. A new and disagreeable kind of pollution was thus added to urban living in such cities as London, Birmingham, Paris, Brussels, Essen and the Ruhr Valley in general, New York, Philadelphia and, later, Pittsburgh. This kind of plague has now spread to Tokyo, Buenos Aires, Mexico City and wherever the advantages of industrialization have outrun the means and the will to control the harmful consequences. During the more recent decades, beginning in the United States after the First World War, then in western Europe and Japan after the Second World War, the rapid multiplication of motor-cars, trucks and omnibuses has added a new dimension to the urban air pollution problem. Combined with traffic congestion during the morning and late afternoon commuting hours, the hydrocarbons and other noxious chemicals discharged by motor vehicles have resulted in air pollution levels that endanger health. The operation of coal- and oil-burning electric power-plants within metropolitan areas has further exacerbated the condi-

\* The original text of this paper (E/CONF.60/SYM.III/18/Rev.1) was submitted to the Symposium on Population, Resources and Environment, Stockholm, 26 September–5 October 1973.

\*\* President, Resources for the Future, Inc., Washington, D.C., United States of America.

<sup>1</sup> In the category of more developed countries are included the countries of Europe, Northern America (Canada and the United States of America), Oceania (Australia and New Zealand) and Japan.

tion of the atmosphere. The total effect of these and other forms of air pollution can be cumulative over extended periods in certain topographical and meteorological situations, the prototypes of which are the Los Angeles basin, the Tokyo metropolitan region, and the coal-burning industrial areas of Europe.

4. Water pollution has been a public health problem since the beginning of recorded history. Prior to modern times, the lack of biochemical and medical knowledge barred the way to effective treatment of both water-supplies and sewage; the basis and motivation for sanitary engineering were lacking. Scientific and technological advances made during the past century or so have largely overcome this barrier, so that most cities and towns in the more developed countries now provide potable water. This is not yet the case in either the teeming cities or the rural villages of the developing countries. Water purity standards are generally adequate in Europe, northern America, Japan, Oceania and other more developed areas; and treatment techniques are well established with only a few difficulties and uncertainties remaining, such as controlling certain virus strains and, of course, coping with new kinds of water pollution engendered by new industrial processes and products. Despite a longer record of successful handling of water pollution than of air pollution, the developed countries are still confronted by serious problems of water pollution. Sophisticated industries require a wide range of chemicals and metals, which are discharged into streams, lakes and oceans. Modern agriculture makes effective use of chemical fertilizers and pesticides, which also find their way into watercourses, especially when they are not applied properly to the soil. Population growth, now almost entirely in urban regions, adds both to pure water requirements and to the generation of sewage and waste products. In many places, sanitary and storm drainage systems are not separated, so that during rain storms sewage bypasses treatment plants and discharges directly into streams and other water bodies. Lastly, people in more developed countries are less and less willing to tolerate polluted and deteriorated conditions in rivers, lakes and bays, largely because of their desire for outdoor recreation, such as swimming, boating and sport fishing. As with air pollution, modern economically advanced societies, while pursuing activities that result in more pollution of water, also demand higher standards of water quality. With greater confidence in technology and larger financial resources, expectations about environment quality have outrun performance, and conditions appear to be even worse than they are or used to be.

5. Pollution of the land itself takes many forms, from chemical contamination to physical disfigurement and aesthetic degradation. Along with water bodies, land is the ultimate sink in which pollutants come more or less to rest. In more developed countries, the collection, processing and disposal of solid waste, that is, paper products, discarded metals, glass and plastic

materials, have become major public service responsibilities. In urban areas, even a short interruption of this service can hardly be tolerated. The earlier practice of dumping raw waste on any convenient plot of ground has given way, in most such areas, to rather elaborate and systematic handling of solid waste, with increasing attention to public health, cost effectiveness and landscape restoration. Sanitary landfill sites now are reconstituted as parks, golf courses and even housing developments, all of which open up fascinating prospects for future archaeologists. To some extent, solid waste can be converted into air pollution by burning and into water pollution by dissolving or by direct discharge into water bodies. Burned paper and other materials going up smoke-stacks can be reconverted into solids by means of precipitators, but these solids have to be dumped on land or in the water. A whole complicated series of trade-offs arises calling for systematic analyses and decisions. Solid-waste management schemes that are efficient from the technical and economic standpoints frequently prove unacceptable in political and behavioural terms. These latter factors constrain severely the management programmes that ultimately will be workable, as public officials have discovered repeatedly. As with air and water pollution, regional approaches to solid-waste handling usually will be preferable to trying to cope with the problems on a smaller scale.

6. Yet another kind of pollution has more recently come to prominence as a result of modern agricultural and industrial technology. Inorganic fertilizers—nitrogen, phosphates and potash—have been applied in larger and larger quantities to farm land, especially in the more developed countries. The same is true of a bewildering variety of chemical pesticides, insecticides and herbicides. A number of trace metallic elements have found increasing application in agriculture to restore adequate amounts in the soil. Many of these substances contaminate surface- and ground-water supplies, and some of them are carried through the air later to settle on distant land and water. In large enough doses, they may be injurious to human health or to animals, birds and fish. The fertilizer materials, particularly when carelessly applied to crops, may accumulate in lakes and estuaries causing algae blooms detrimental both to industrial process and to human consumption uses of water, as well as to fishing and outdoor recreation.

7. With the advent of nuclear power and weapons, a certain amount of radio-active substances has found its way into the atmosphere and watercourses. Although damages thus far appear to have been minimal (Hiroshima and Nagasaki apart), the number of nuclear power-plants likely to be in operation in the more developed countries within the next two or three decades poses environmental and health problems of the utmost severity. Even the enforcement of the strictest standards in fuel production and plant operation, and in the transportation, processing and disposal of radio-active

waste cannot provide complete protection against the escape of radio-active materials of very long half-life that are associated with both conventional and breeder fission-type reactors.

8. Lastly, attention should be called to oil spills, deliberate or accidental, which have now reached the magnitude of a threat to the quality of the oceans and shorelines of the world. This threat is concentrated in harbours and bays where oil is shipped and in the straits and passages through which tankers ply. Other more toxic materials, such as mercury compounds or possibly carcinogenic substances associated with tailings from taconite mining, are occasionally discharged into water bodies.

9. Another set of environmental problems, occurring principally in the more developed countries, has to do with the deterioration of certain amenities of living—enough space and a lack of congestion, adequate parks and nature preserves, a minimum of noise and objectionable odours, a sense of orderliness and visual delight in both towns and countryside. As incomes continue to rise in Europe, Japan, Northern America and the few other more developed regions, increasing numbers of people are placing a high value on the aesthetics of environmental form and function and on the harmonizing of human activities with nature. In reaction to the excesses of urban, technological living, many persons, especially youth, have turned to a search for lifestyles which emphasize slower rates of growth and change, simpler forms of behaviour, serenity of spirit and wholeness of personality. Back-to-nature movements, whether inspired by Rousseau or Thoreau, have invariably lacked staying-power and have soon died out in practice, although their intellectual and emotional influence continues to be felt. More hopeful of success would be a social movement directed towards incorporating, in muted degree, elements of the new lifestyles with the inevitable complexity and fast pace of the Western type of industrialized society, so as to achieve a more humanized and sustainable future. Much will hinge on better planning and design for such a future and on the social discipline and control needed to bring it about.

#### SOURCES AND CONSEQUENCES OF POLLUTION

10. The sources of environmental pollution in the more economically advanced countries are not hard to locate, nor are the larger and more immediate consequences. The delayed consequences, for example, of air pollution on health, are more subtle and difficult to gauge. The first and obvious pollution source is the growing population, which in various more developed countries has increased by anywhere from one fourth to more than double during the past three decades. To be sure, since the post-war "baby boom", fertility rates in most such countries have been falling and now are generally close to a net reproduction rate of one, signifying a long-run tendency for the population merely to reproduce itself. Absolute numbers, however, will

continue to increase even if the unity reproduction rate is sustained—for as long as 70 years in the United States of America, for example—as the bulge in the age structure of the population now in the childbearing years works itself out. Clearly, if *per capita* amounts of pollutants and wastes were to remain constant, the residue loading of the environment would rise precisely with population. Within limits this is acceptable, given the capacity of air, land and water to absorb, dilute, carry away and otherwise render pollutants harmless; but in many places these limits are being approached or have been exceeded.

11. In many respects, more significant than the total number of persons is their distribution over the land. Counting all the more developed countries of the world, one finds that on the order of two thirds of their population is urban. For the United Kingdom of Great Britain and Northern Ireland, and for Sweden, the percentage approaches 80; for Japan and the United States, it is about 70; for the Union of Soviet Socialist Republics and Poland, more than 50; and for Australia, well over 80. Pollution and environmental degradation generally are worse in urban areas, which continue to grow more rapidly in population than countries as a whole. In the United States especially, but also in other more developed countries, urban growth is taking place mainly in the suburban rings, not in the central cities. However, air and water pollution and solid-waste disposal tend to be regional in scope, so that this intra-metropolitan pattern of movement and growth does not significantly reduce most kinds of environmental damage. In certain respects, the problems are intensified; for example, sewage collection systems, or, alternatively, individual septic tanks, are considerably more expensive in the more sparsely populated suburbs than in central cities, as is the collection of solid waste. Obviously, congestion and sheer crowdedness is greater in urban areas giving rise to numerous environmental and social problems. Yet, with good city planning and enough funds to provide preventive and corrective measures to maintain a healthful and attractive environment, plus the will and discipline to do these things, it should be possible to sustain an acceptable urban existence for even a few more people. This could be achieved by a further modest growth of cities and metropolitan regions already quite large, by the encouragement of greater growth in medium and even small cities, and by the establishment of a number of carefully located new towns.

12. Although the matter is under dispute, it would appear that the level of production and consumption, plus the kind of technology and products involved, are the principal sources of pollution and environmental disruption. *Per capita* national production and income correlate quite well with various indicators of pollution, such as energy use (particularly coal and petroleum), pesticides and commercial fertilizers, paper and paper products, production of chemicals, iron and steel and synthetic products in general. Furthermore, the more

developed the economy of a country becomes, the more rapid is the annual growth rate for the more polluting products, including plastics, motor fuel, glass bottles and synthetic organic chemicals. Industry tends to be concentrated in the same places as population and consumption, thus intensifying environmental problems in urban areas, such as the Ruhr region of the Federal Republic of Germany, the Midlands of England, the industrial area of south-western Poland, the north-eastern megalopolis of the United States and the Tokyo-Osaka region.

13. The two general indicators of pollution sources, or latent environmental degradation, therefore, are population density, especially urban population, and *per capita* gross national product (GNP), which is generally a result of industrialization. As a country or region moves towards higher levels in these two respects, it is increasingly likely to undergo environmental deterioration, that is, air and water pollution, solid-waste disposal problems, crowding etc., unless countervailing measures are taken to prevent or abate these harmful effects on the environment.

14. The table given below shows some of the indicators of pressures on the natural environment for a wide cross-section of developed and developing countries, and for all the developed countries and all the developing countries taken together (excluding those with centrally planned economies). Data for developing countries are included primarily to bring out the contrast between them and the developed countries with respect to environmental factors. In the first set of columns are population density, urbanization and gross national product. Population density and GNP are calculated in relation to agricultural areas, as well as to total area of each country, in order to show pressures on land that is more intensively used. Mere surface area has limited relevance to either production or pollution problems, especially for such countries as Australia, Brazil and Egypt. It can be seen that, contrary to much conventional thinking, there is little if any correlation between population density and levels of income. Although incomes are low in densely populated countries like India and the Philippines, equally low incomes are found in countries with low population densities, such as Brazil or Zaire. Moreover, some of the highest income levels are in the countries with the greatest population densities, such as Japan and the Netherlands. Two columns of the table show that there is no over-all significant relationship between the level of income and the availability of land. There are, however, wide differences in urbanization and in output *per capita* and per hectare between the developed and developing countries. These differences account for significantly different burdens on the natural environment. As figure I<sup>2</sup> shows, urbanization and high incomes are positively correlated. Both move up to-

gether, causing pollution problems to rise at a far greater speed than urbanization alone. Excluding a few anomalies, such as Israel, Kuwait and perhaps Ireland and Greece, all of the more developed countries have more than half of their total population in urban areas and a *per capita* GNP of more than \$800.

15. The last four columns of the table show some indicators of particular types of pollution: fuel consumption as the principal source of air pollution; paper and board consumption as an indicator of solid-waste problems; and fertilizer and insecticide use as an indication of land and water pollution arising from agriculture and health measures. Other indicators that might be used include wastes discharged into streams and lakes, scrap-metal output and sulphur and other pollutants discharged into the air. Each of these specific indicators of pollution, as well as many others, is more or less closely associated with the two general indicators, population density and *per capita* production.

16. In figure II the relationship between *per capita* GNP and *per capita* energy consumption is shown. The correlation is rather high, and the regression line is steep, showing that *per capita* energy consumption rises about fiftyfold for a tenfold increase in *per capita* GNP. Figure III shows a similar relationship between GNP and paper usage. Similar diagrams could be drawn, relating other specific measures of pollution to GNP *per capita*, population density or some other aggregate. It seems clear from figures II and III that rising income levels tend to add pressure on both the supply of raw materials and the condition of the environment—both in quantitative and qualitative terms—more rapidly than does increase in population. It is also clear that higher incomes add to the ability to combat pollution and to produce substitute materials.

17. Inseparable from economic advance is modern technology, plus the financial, managerial and labour resources with which to apply it in industry, mining, agriculture, animal husbandry, forestry, fishing and the wide variety of accompanying services. Wherever one looks in the more developed countries, one sees machinery and production methods that are potentially, if not actually, highly destructive to environmental quality: giant strip-mining shovels, subsonic and now supersonic jet aeroplanes, millions of motor-cars and trucks (over 100 million in the United States and an annual production of 10 million), clear cutting and other forestry practices, factory vessels for ocean fishing, nuclear reactors, numerous applications of chemistry and biology in production. These are a few examples that come quickly to mind. To the historic revolutions in agriculture and manufacturing, which began nearly 200 years ago, have been added the revolution-like changes of electric power, scientific management, nuclear power and heat, operations research and com-

puter control of production processes and the development of a myriad of synthetic products from relatively common raw materials. The pace of technological innovation seems always to quicken and to be on the verge of outstripping man's capacity to govern, channel and control what is happening. The mere thought of the problems piling up in front of him has created what has been termed "future shock", which is now felt, in varying degrees, by nearly everyone in more economically advanced countries.

18. Ironically, the solution of many of the environmental problems resulting from technology requires the application of yet more technology. For example, the

petrol-powered internal-combustion engine yields the major share of air pollution in the urban areas of the more developed countries (nearly all of the carbon monoxide and most of the hydrocarbons). But the more feasible correctives require new technologies, such as afterburners, stratified charge designs, the Wankel, fuel cells and steam-engines. The full environmental effect of a new technology is frequently difficult to assess and may turn out to have a result opposite to that intended. The catalytic converters to be required by 1976 on all motor-cars produced in the United States appear likely to increase fuel consumption per mile to such an extent as to negate much of the very advantages that were to

Figure II. Per capita energy use and gross national product, 1963

Note: Excluding centrally planned economies.

Figure III. *Per capita gross national product and per capita consumption of pulp and paper*

be achieved in the reduction of air pollution, and, at the same time, to eat still more into dwindling supplies of petroleum. In this case, some environmental quality improvement is being won at the expense of a diminution of raw-material quantity. The total environmental bill for a new technology needs to be reckoned and then compared with the total bill of alternatives, including the way the function is currently being performed. It has been noted already that much of recently applied technology, as well as that now in sight, appears to have environmentally perverse results on balance, with the relatively rare, non-degradable and toxic supplanting the more common, degradable and benign materials (for example, detergents for soap and plastics for paper.)

19. In addition, social and behavioural traits now common in the more economically advanced industrial and post-industrial societies account, in significant measure, for the accelerated deterioration of the natural environment. As producers, people in such societies greatly prefer to use machines and electric power rather than their own human labour. For transportation, they prefer the speed and comfort of aeroplanes, trains, motor-cars, trucks and omnibuses to horse-drawn vehicles. As consumers, they prefer plastic containers, chemical solvents and throwaway bottles. Modern urban families live in a dispose-all system: everything neatly disposed of from their point of view, but still to be coped with by the community at large. Large differences persist in matters of personal attitudes towards the environment; Scandinavian standards of cleanliness and order seem high to visitors from other places, for example. No doubt it will prove to be extremely difficult to reverse trends in habits of behaviour such as those indicated here, even with the prodding of incentives and penalties. One wonders if elements of the recent ecology and zero growth movements will take root and flourish widely and rather hopes they will. Care of the environment and thought for the future are largely personal matters with which each individual must come to terms. Until changes of this kind come about and are built into behavioural patterns and given institutional sanction, progress in environmental improvement will be slow and hard to sustain.

20. Estimates of particular kinds of air and water pollution in the year 2000 have been prepared for the United States under several different assumptions as to future population and gross national product:<sup>3</sup> Figure IV presents high (approximately three-child families) and low (approximately two-child families) estimates for 2000 and 2020. Corresponding estimates are also shown for GNP and GNP *per capita*, with four combinations of high and low population and GNP figures. The high GNP is substantially above that which would

result from a straight projection of the long-term annual average rate of increase; the low GNP is slightly below the long-term projection. The two higher projections (high population-high GNP and low population-high GNP) serve to reveal alternative possible futures that would tend to place relatively severe strain on the environment, as well as on supplies of raw materials. The two lower projections represent easier situations.

21. The air pollution consequences (particulates, hydrocarbons and oxides of nitrogen) and the water pollution consequences (biochemical oxygen demand, suspended solids and dissolved solids) are depicted in figure V. Each of the four futures is shown here in terms of three different assumptions as to technology and policy. The most striking (and hopeful) prospect revealed in these estimates is that with production and treatment processes that would probably be induced by an active pollution abatement policy, the amount of pollution generated and emitted in the year 2000 would be far, far less than under the alternative assumptions and for most of the pollutants even less than the actual amounts for 1970. According to this way of examining the future of one highly developed country, vigorous policies for preventing and abating pollution can make a decisive difference. It has to be recognized, of course, that any positive and continued rate of increase of pollution or environmental damage, even if it does not commence until after 2000, will ultimately lead to disaster. But in the longer run of the twenty-first century and perhaps beyond, human behaviour, not to mention laws and institutions, can change markedly. For these adjustments, time is of the essence and policies that buy time are desirable.

22. The consequences of pollution and environmental disruption, certainly in their modern, high-technology, synthetic-compound form, have been far more severe in the more developed than the less developed countries. The harmful results are indicated, in part though not in full, by effects on human health, natural ecological systems, economic functions, social welfare, amenities and aesthetic factors. Those effects which are long-lasting or irreversible, widespread, multiplying over time in intensity and lethal or highly damaging are, of course, the most significant. Pollution and related effects may be arrayed according to their severity: those which disarrange the genetic structure of human, animal or plant life; those which undermine or distort basic ecological support systems or climate; those which are harmful to health and otherwise impair the functioning of people; those which diminish the aesthetic quality of the environment and the way people have to live; those which are costly in money and effort to prevent or correct; and those nuisances which reduce the social amenities and delights of living in a clean and ordered environment.<sup>4</sup>

<sup>3</sup> R. G. Ridker, ed., *Population, Resources and the Environment*, vol. II of Commission research reports of the Commission on Population Growth and the American Future (Washington, D.C., Government Printing Office, 1972). The estimates are based on a dynamic 185-sector model of the United States economy (the University of Maryland Inter-Industry model) developed by Clopper Almon.

23. Statistical indicators of pollution effects abound but, unfortunately, are not yet available on either a comprehensive or comparable basis for the countries of the world, or even for the more developed countries. The establishment of new environmental programmes and agencies, in the more developed countries especially, promises that the deficiency of such indicators will

soon be reduced. International agencies and, in particular, the United Nations Environment Programme, will be looked to for leadership in this activity without which it will be difficult to keep track of what is happening to the condition of the environment. Systematic monitoring of the amounts of pollutants in sufficiently fine detail will be difficult, but simple compared with translating

statistics concerning sulphur oxides in the urban air, biochemical oxygen demand in the water, or carbon dioxide in the upper atmosphere into their effects on human health and welfare or on the viability of ecosystems. Coefficients that relate health and other conditions to the incidence of a particular pollutant, or to symbiotically related pollutants, are generally crude and inadequately verified. Even less clearly established are measures of risk-benefit relations, which define the uncertainties involved in finding answers to the question of how much risk may be justified to obtain a particular benefit. Further efforts are also needed to state the private and social benefits and costs in economic terms that will be helpful in making decisions with regard to alternative courses of action. In this latter connexion, care must be taken that non-economic information is given proper weight in decisions, especially those dealing with very long range factors, the benefits and costs of which are hard to measure. The process by which environmental decisions are made and the significance accorded different kinds of evidence and argument are more important than detailed numerical calculations.

24. No extended consideration of the various consequences of a polluted environment is presented here, but their ultimate importance and the necessity for monitoring them closely is noted. Nor has there been an attempt to delineate how these consequences bear differently on the several more developed countries or within each country on different regions and social groups. Obviously, as mentioned earlier, most pollutants are concentrated in the urban areas where, in most of the developed countries, well over half the national populations live. The poor in every country suffer more from environmental degradation, because they tend to reside and work in central cities, where air pollution, traffic congestion, solid-waste problems, poor housing and lack of recreation facilities are concentrated, rather than in suburbs. Furthermore, the poor are less able to escape or buffer themselves from these conditions.

#### POLICIES FOR ENVIRONMENT IMPROVEMENT

25. Considering this survey of environmental problems, sources and consequences in the more developed countries, one may ask what lines of policy, what broad programmes, would be helpful in preventing and abating pollution and arresting further deterioration of the environment. One clue can be found in the analysis of some principal sources or causes of pollution. The two basic factors which, at least in an incipient way, make for environmental quality problems are population density and *per capita* production (or income). Evidence such as that presented in figures I-III, relating population and production to such pollution-associated activities as energy consumption, indicates that the more densely populated and highly industrialized countries have incipient conditions for greater environmental pollution. Less industrialized and less densely populated countries can

gauge from such scatter diagrams their own likely path towards pollution as they grow in population and industry, assuming they actually do follow the growth patterns of the more developed countries.

26. Whether the more developed countries are actually experiencing more—or less—environmental pollution than less developed countries is a complex question. If investment and other efforts to abate or prevent pollution were the same in both, then environmental conditions would no doubt be worse in the more developed regions. As things now stand, however, people in the less developed regions seem to be worse off. Their water-supplies are usually less pure, both solid-waste and sewage problems are severe, housing conditions very bad and public health levels low. Densely populated urban slums and poverty-stricken rural villages alike are characterized by physical environments of generally poor quality, although specific conditions vary from one situation to another. In the large cities of less developed countries, air pollution and congestion will typically be worse than in villages; but public health services, water-supply and job opportunities will be better.

27. Turning again to the more developed countries, it appears likely that some further reduction in fertility rates moving towards the maintenance of unity net reproduction, where this has not already been reached, will contribute to a cleaner, more healthful and acceptable environment. This will be true especially during the years immediately ahead, when the cohorts of children will be relatively small and the cohorts in the working ages relatively large. Indicated policies include more vigorous family planning, changes in income-tax deductions and in other tax law provisions which favour having children, replacement of anti-abortion laws with carefully regulated abortion on a voluntary, medically sound basis and informational and educational programmes designed to encourage people to want small, maintenance-level families.

28. In the more developed countries, increasing production and consumption *per capita* account for a greater load of pollution than does increasing population. With national production rising at from 3 to 8 or 9 per cent per annum in these countries and with population rising at 1 per cent or less in most of them, it can be seen that economic growth is responsible for the major part of additional pollution. In this situation, there is some logic in advocating a policy of slow, or even zero, economic growth. Such a course, unfortunately, presents serious problems for poor people (and for depressed industries and regions) who could gain only at the expense of the more affluent. A shift to zero growth would also have profound implications for new investment and other dynamic features of both free enterprise economies and centrally planned economies. It would entail institutional and behavioural changes, the nature of which can be visualized only dimly. Even so, policies to check rates of economic growth at the higher end of the scale would appear desirable, especially if

such rates are thought to be difficult to sustain and if they involve distortions of normal investment-consumption patterns. Active pollution abatement efforts are strongly indicated in any case.

29. Fortunately, not all economic growth adds significantly to pollution, so that zero growth is not necessary on this account. As stated earlier, pollution results mainly from particular, identifiable raw materials, particular industrial and agricultural processes and products and particular modes of consumption. Internal combustion engines, coal- and oil-burning plants for generating electric power and a few other activities account for most of the air pollution. Industries producing pulp and paper, certain chemicals, food-processing, iron and steel, and a few others give rise to much of the water pollution in more developed countries. Curtailment of these industries is not so necessary as are strict standards on emission and discharge of pollutants, the redesigning of processes and products and the substitution of less polluting raw materials. These circumventions require capital funds, research, labour skills and an extensive technological base from which to work. The indicated policies include vigorous research and development, emission charges or penalties to reduce pollution from particular sources and strict and fair enforcement of environmental standards.

30. Most anti-pollution policies and programmes will be national in scope; but some, to good advantage, can be *intra-national* and some *international*. Within countries, settlement patterns and the location of certain industries can be influenced so as to reduce pollution and disfigurement of the environment. Transportation routes and utility lines can also be planned with the same end in view. A basic issue is whether to concentrate waste generating activities primarily in cities, so as to be able to deal with waste more economically, or to disperse such activities, so as to equalize waste loading over the whole country. At the *intra-national* level regional approaches make good sense: the river basin for water pollution; the air shed for air pollution; the metropolitan area for traffic congestion; housing and community planning; and solid waste disposal. Modern computerized systems analysis, frequently embracing atmospheric, hydrological, demographic, technological, economic and even social subsystems, can be used for understanding these matters and appraising the relative merits of alternative policies. In such instances, it will typically be found that new laws, institutions and administrative organizations are necessary to deal successfully with these regional situations. Many examples of the regional approach, both existing and contemplated, come to mind: the Ruhr, the Rhine valley, the Po, the Thames, the Delaware; the air sheds of London, Paris, Tokyo, Moscow, New York, Los Angeles; and numerous agricultural and forest regions.

31. International approaches to pollution problems will also be helpful and, in certain cases, necessary if progress towards a better world environment is to be made. The more developed countries, where many of

these problems are acute and which have greater financial and technical capacity for solving them, must take the lead. International initiatives are called for or need to be strengthened in response to several challenges.<sup>5</sup>

32. Much can be learned through exchanges of experience at the national and *intra-national* levels in trying to improve the environment, whether by means of limiting population growth, redirecting technology, penalizing pollution-causing activities, altering the location of industries and settlements, developing cleaner sources of energy and more efficient modes of transportation, or creating new regional institutions for pollution abatement.

33. Many river basins and air sheds spread over more than one country. Co-operative schemes are necessary, not only for gathering hydrologic data and measuring the amounts and occurrence of pollutants, but for apportioning and managing water-supplies, sewage discharges, atmospheric loadings of pollutants, location of polluting activities and provision of outdoor recreation and other amenities. Effective incentive, penalty and enforcement programmes will also have to be undertaken on a co-operative basis.

34. Certain pollutants spread more or less rapidly over whole continents or even the world. Those which are highly toxic or which may seriously distort major-support ecosystems require international control based on reliable monitoring. Obvious examples are radioactive isotopes, DDT and other chlorinated hydrocarbons used primarily as insecticides, carbon dioxide in the upper atmosphere (about the effects of which there continues to be dispute), oil spills principally from tankers and off-shore drilling operations and perhaps heat discharges from electric generating plants and other sources. Most of these pollutants have potentially deleterious effects on atmospheric, ocean or meteorological systems and are continental or world wide in scope. Especially in need of control are those effects which are irreversible, long-lasting and widespread in their effects.

35. Next in line for consideration are those internationally traded goods (or services) which, in some sense, embody pollutants. If this embodiment is taken literally and the traded product is actually contaminated, the case for import prohibition or control is clear. If, however, the traded article embodies a pollutant only in the sense that it was produced in a way that resulted in an amount of pollution in the country of origin which would be unacceptable in the importing country whose own competing industry has to meet higher standards, then the case for international control is less clear and presents difficulties. "Pollution havens" in less developed countries (or in more developed countries for that matter) will be resented in importing countries that enforce high environmental standards. Yet, industrial

<sup>5</sup> C. S. Russell and H. H. Landsberg, "International environmental problems—a taxonomy", *Science*, vol. CLXXII, No. 3990, pp. 1307-1314.

areas in less developed countries typically have far fewer chemical forms of air and water pollution and, of course, are in greater need of industrialization as a means of raising material levels of living. A reasonable argument could be made for an international agreement to permit greater discharge of pollutants in less developed countries, varying the amounts inversely with average *per capita* incomes. In this way, as a country became more industrialized and richer, it would have to apply higher environmental standards to the production of internationally traded goods. Such an approach would have to be elaborated carefully with regard to the differences among both pollutants and countries. Possibly a programme of this kind could be launched first among the more developed countries with other countries joining later.

36. No doubt the international community of more developed countries could be more ingenious in devising incentive, regulatory and educational programmes for promoting environment improvement among themselves. Loans, technical aid and exchange, and joint training and demonstration activities are among the ways for doing this. Both international agencies and multinational firms, as well as international labor unions, professional organizations and political pressure groups, could play a role in this.

37. Lastly, an intensification of co-operation among the more developed countries in research and development promises high returns in environmental protection. Here, the possibilities for joint action are open and invite further attention by ecologists, engineers, economists, sociologists, planners, industrialists and many others.

38. The costs of an adequate programme of environmental improvement for the more developed countries are difficult to estimate, not only because of technological and economic uncertainties, but because the expectations people have for a cleaner, less polluted environment continue to rise. A programme of public and private outlays for the next decade or two in the United States of America might amount to 2 or 2.5 per cent of the gross national product, compared with around 1 per cent in 1972. In dollars, this would represent an increase from \$12 thousand million to between \$24 thousand million and \$30 thousand million, and would rise in the future with a growing GNP. Over a 10-year period, this would mean an expenditure of up to some \$400 thousand million. Some relatively small portion of this is likely to be made available for strictly international programmes. These amounts could turn out to be much larger, depending upon future events. If the other more developed countries were to devote a comparable portion of their GNP to environmental programmes, the total expenditures of all the more developed countries would reach well over \$1,000 thousand million and perhaps as much as \$1,500 thousand million. Much of a comprehensive anti-pollution programme would not require governmental, or even private, outlays, but would be accomplished by means of process changes in industry and agriculture and behaviour

changes by people that in the end would involve no net increase in cost and might even result in cost reductions. Programmes of this magnitude could be financed out of general or specific revenue sources of governments, private firms and individuals. The government portion, in part, could come from special pollution emission or discharge taxes. International financial requirements could be met, in part, from general sources available to the United Nations or other organizations. Possibly new sources could also be tapped, such as a modest charge on international oil or other shipments or from rents on the exploitation of the common property resources of the oceans.

39. It is difficult to draw simple, direct conclusions about population from environmental conditions. Major factors intervene, such as technology, settlement patterns, social infrastructure, private investment, consumption patterns and political institutions, to name a few. Despite all this, by way of summary one can indicate a few broad positions and policies that make sense concerning population policies for more developed countries.

40. First, most of the more developed countries have arrived at a demographic condition in which the long-run tendency is towards population stability, or very nearly so. This being the case, no additional policies or measures of a positive nature are called for, except possibly a somewhat more energetic pursuit of existing efforts to reduce birth rates and, thereby, to reduce the absolute increase in population caused by the bulge in the number of persons in the childbearing ages. Unwanted births, especially, should be reduced. Demographic factors should be monitored closely. If net reproduction rates start moving upwards again, appropriate actions to check such movement should be taken promptly. Plans for doing this should be kept in readiness, covering such matters as tax advantages for small families, free contraceptives and perhaps abortions in specified circumstances and accelerated information and education for birth control.

41. Secondly, settlement patterns and industrial location may be influenced by deliberate policies in ways that reduce harmful environmental disruptions. Several alternatives are possible. Metropolitan areas could be organized more compactly, for example, along a few high-density corridors, to reduce the need for air-polluting private motor-cars and to permit more efficient handling of sewage and solid waste. Or, future population and industrial growth could be guided away from existing large cities to dispersed smaller cities or new towns. This alternative may entail the loss of large-scale economies, which would have to be traded off against environmental and other benefits.

42. Thirdly, environmental pollution and disfigurement appear to hurt the poor more than others in the population. The poor are concentrated in and near the urban centres where air pollution, congestion, noise and solid waste are also concentrated. In addition, the poor are less able to move away from an undesirable environ-

ment, permanently or temporarily, or to buffer themselves from its effects. The remaining poor in the more developed countries are located in rural, depressed areas, depending upon depleted resources, such as high-cost coal mines or marginal agriculture. As with other policies, environmental policies should take special care to improve first the condition of the poor, thus redressing somewhat the distribution of real income, including qualitative components, in their favour. The payment for such environmental improvements through general tax revenues (especially income taxes and property taxes) will tend to benefit the poor differentially, as will payment through inclusion of environmental costs in the selling prices of goods and services (especially of luxury goods and services). However, there are more direct and effective ways of improving the lot of the poor than by environmental policies; for example, by income supplements, social insurance, and health and educational benefits.

43. Fourthly, an attack on environmental pollution and disruption through population policy, at least in the more developed countries, is likely to be clumsy and far less effective than a more direct attack through environmental policies. These policies should be broad and diversified and should depend upon the particular problems, economic capacities, social institutions and political realities of the various countries. As a general policy, there is much to be said, as mentioned earlier, for a policy of including environmental costs, to the extent that they can be determined, in prices. Schedules of emission charges levied on specific pollutants offer advantages in this regard principally by minimizing distortions in price competition and factor allocations. Other environmental disruptions, certainly those of a severely damaging or lethal character, will have to be prohibited outright with the highest penalties for disobedience. Where the sources of emission are hard to locate, the feasible approach is to set ambient standards and then ration permitted loadings of pollutants or tax over-loadings progressively. An even better approach for the longer run is to establish incentive schemes (tax

preferences, research and development assistance, access to raw materials and markets etc.) to encourage new technological processes which will bypass environmental damage altogether or induce recycling and reclamation of waste materials.

44. Fifthly, population problems encompass more than those of gross demographic trends, of poor people, of settlement patterns and of technological or economic matters. Population policy must deal with more than these elements. Especially important are those policies which attempt to deal with the effects of environmental disruption on longevity; on particularly vulnerable groups, such as the elderly, youth and handicapped; on work performance of the labour force, on the physically and mentally ill, on accidents and ultimately on the enjoyment of life and human freedom. Medical scientists, psychologists and philosophers can contribute to an understanding of population aspects of these matters.

45. Lastly, despite many similarities, profound differences exist and will continue to exist for a long time between the more and the less developed countries. These must be understood and taken into account when formulating population policies for more and less developed countries and to some extent on a global scale. The twin objectives of zero economic growth (at least reductions in economic growth) for the more developed countries and zero population growth (at least reduced population growth) for the less developed countries are attractive as general, long-term directions in which to move. Much analysis, experimentation and education undoubtedly will be necessary if the population and economics of the world are to unfold along these lines. At any rate, one conclusion seems clear: population policies in the more developed countries (and resource, environment and economic policies as well, for that matter) should be conceived and put into operation only after considering most carefully their likely effects on the less developed countries. Those policies which serve the proper concerns of the less developed countries, as well as those of the more developed countries, are greatly to be preferred.

## ENVIRONMENTAL PROBLEMS OF THE DEVELOPING COUNTRIES \*

S. H. Ominde \*\*

1. A critical examination of the contemporary world shows two very contradictory tendencies in the intellectual concern and practical approach to world problems. First, there is a global feeling of hopelessness in the face of conflicting and at times opposed international interests. This is the world of national development and safeguarding of the national identity and integrity. It is the raw material of international politics and events that permeates day-to-day concern of the international community.

2. In the second place, there is emerging an increasing global concern for the context of man's development problems on the spaceship earth. The second is the stark reality of a world of widening international and national disparities in incomes and living opportunities. At the national level it is expressed in the mounting criticism of the gross national product (GNP) as a measure of national development. At the international level, there is increasing condemnation of the deepening gap between the affluent and the indigent countries and the persistent failure of the human community to resolve the dilemma through existing institutions.

3. Within a relatively short period of time, the world has been thrown into an intellectual ferment in conceptualizing problems which earlier were only seen dimly but which, with increasingly effective techniques of measurement and analysis, are becoming staggering in proportions. Central to these developments is the theme of population and environment. In this process, the world has been exposed to some of the most striking dimensions of the continuing drama of man's survival on the planet. What is referred to specifically here is the intense activity which culminated in the United Nations Conference on the Human Environment at Stockholm in June 1972.

4. There is yet a further characteristic trend of which mention should be made. This is the observable narrowing of the gap between the analysts of the problems and the policy-makers on the two vital issues of population and the welfare of man as a global goal. But welcome as these developments are, the concern with these vital issues is still confined to a small minority of mankind and a minority of countries. The vast majority

of the countries of the world are approaching and involved in the crisis with an incredible lack of concern. This is indeed an over-statement of the problem. But, it is a needed caution to underline the need to increase the global, national and individual awareness of the issues at stake. Considerable progress has been made during the decade of the debate. Out of the critical thinking has emerged a clearer view of the nature of development, the nature of the population problem as it affects the regions of the world, individual countries and the persons for whom those countries are planning.

5. From the conceptual point of view, the United Nations Conference on the Human Environment represented a milestone in the definition of the concept of development. At the Conference, nations of the world became aware of the need to recognize the legitimacy of a developing world view of development and its problems. A divergent approach to environment and development which encouraged speculators to forecast irreconcilable differences between the affluent and poorer countries of the world was resolved. It was resolved through a fundamental consensus on the concept of development and in particular on the acceptance of the special role and character of the population problem in development.

6. The Conference at Stockholm raised the basic distinction from the environmental point of view between the development problems of the high technologies and those of the developing world.<sup>1</sup> Development impact on the environment for the developed regions of the world was seen in terms of problems of production costs which disregarded external diseconomies, the pressure of modern urbanization and the risk of scarcities in materials and energy as a result of the exponential growth. To the developing world, the environmental issue focused attention on changes triggered by the population crisis and the related problem of lack of development. For the developed regions of the world, the United Nations report on development and environment had this to say on the outcome of a high level of economic development:

"The creation of large productive capacities in industry and agriculture, the growth of complex

\* The original text of this paper (E/CONF.60/SYM.III/11) was submitted to the Symposium on Population, Resources and Environment, Stockholm, 26 September-5 October 1973.

\*\* Professor of Geography, University of Nairobi, Nairobi, Kenya.

<sup>1</sup> B. Ward and R. Dubos, *Only One Earth: the Care and Maintenance of a Small Planet* (New York, W. W. Norton, 1972), pp. 46-145; D. H. Meadows and others, *The Limits to Growth: a Report for the Club of Rome's Project on the Predicament of Mankind* (New York, Universe Books, 1972).

systems of transportation and communication, the evolution of massive urban conglomerations, have all been accompanied in one way or another by damage and disruption to the human environment.”<sup>2</sup>

7. But while recognizing the commonality of problems of development and the need to take them into consideration for future planning, the development problems of developing regions were emphatically stated in the report in these terms:

“However, the major environmental problems of developing countries are essentially of a different kind. They are predominantly problems that reflect the poverty and very lack of development of their societies. They are problems, in other words, of both rural and urban poverty. In both the towns and in the countryside not merely the ‘quality of life’ but life itself is endangered by poor water, housing, sanitation and nutrition, by sickness and disease and by natural disasters.”<sup>3</sup>

8. Other indexes are drawn upon below to underline the distinctions mentioned. But the one concerning capital must be stressed here. Many countries of Asia, Africa and South America have been experiencing an acute shortage of capital for investment in development programmes. It is estimated that Asia, with over half of the total world population, can claim only one tenth of the world’s national income. North America, with less than 10 per cent of the world population, accounts for nearly 45 per cent of the world’s national income. Asia, Africa and South America together account for well over two thirds of the world population, but receive only 15 per cent of the world’s national income. The remainder, with only 35 per cent, receive about 85 per cent of the world’s national income.<sup>4</sup>

9. However, it would be misleading to rank the United Nations Conference on the Human Environment as providing an opportunity for the world regions to underline their differences. The warning that the problems arising out of the process of development are also in evidence in developing countries should be noted. The basic conference document underlined the specific role of population in the following terms:

“The very growth of population when not accompanied by adequate economic development, brings out the prospect of rising unemployment further impoverishing the countryside and swelling the drift to the towns and creating human problems of the deepest intensity. They can only aggravate the serious social and political tensions that even now prevail in these societies.”<sup>5</sup>

<sup>5</sup> “Development and environment”, *loc. cit.*, annex I, para. 9.

10. These are the problems that strike at the very roots of international peace, the harmonious development of individual countries and, in particular, man’s effort to rise above the level of penury which afflicts the greater proportion of humanity.

11. This paper considers first the global, regional and national dimensions of the problem of population with special reference to developing countries. In the following sections, attention is directed to the consequences of the problem to development objectives, the severity and the likely trend. Lastly, consideration is given to the possibilities that technology offers at the international and national levels to the solution of the problems.

#### POPULATION PROBLEMS OF DEVELOPING COUNTRIES OF THE WORLD

12. Concern with the interrelationship between human numbers and human welfare is not new. It is the environmental component of the problem that is a relatively new dimension. Both are problems which, for specific reasons, could only be stated with clarity in the twentieth century. It is the twentieth century that produced the technology which brought the population problem to the forefront of international concern. Further, it is the combined effect of international and national efforts towards more accurate population information in the twentieth century that now permits a statement of the population problems and their solution with a tolerable degree of precision. In this context, one must first take up a statement on the current situation from two scholars who have contributed a great deal to public awareness of the problem in the twentieth century.

13. Ehrlich, continuing his crusade initiated with the publication of his book, *The Population Bomb*, sees the global crisis in the following terms:

“The human population is not only too large, it is growing at a mind-boggling rate—about two per cent per year. At this rate, the population doubles every 35-40 years. Every year seventy million people are currently being added to this planet—every three years an equivalent of the United States to feed, clothe and house.”<sup>6</sup>

14. Of the consequences, he pointed out that roughly 15 per cent of the people in the world live in affluence and that about 60 per cent live in utter misery and the remainder are on the border line. He goes on to say:

“Hunger and malnutrition are most prevalent in the underdeveloped world, where birth rates are high and the majority of the people live in poverty. Most vulnerable to both hunger and malnutrition are young children and mothers. Protein malnutrition in pregnancy, infancy and early childhood can result in

<sup>6</sup> Paul Ehrlich, “The population crisis: where we stand”, in Noel Heinrichs, ed., *Population, Environment and People* (New York, McGraw Hill, 1971), p. 8.

permanent stunting of growth and damage to the brain if the child survives. High infant and child mortality rates in part reflect the high incidence of malnutrition in underdeveloped areas.”<sup>7</sup>

15. Hauser, as a corrective to undue emphasis on excessive fertility and excessive rates of population growth, has underlined three dimensions in the global aspect of the problem. These dimensions are: the accelerating rate of population growth during the three centuries of the modern era; the increasing concentration of the peoples of the world on relatively small portions of the earth or urbanization; and the heterogeneity of peoples increasingly being forced to share the same life space.<sup>8</sup>

16. Summing up the regional aspect of the problem to the United Nations Conference on the Human Environment in Stockholm, the Secretary-General of the United Nations referred to it as the problem of the “North” and the “South”:

“Everything is of concern to everybody in our deeply interdependent world today. The South is preoccupied that a reduction of growth in the North might lead to a reduction of their exports of raw materials which is their lifeline to progress. The South is also beginning to realize that the North which consumes two thirds of the world’s resources might damage irremediably the oceans, the earth and the

atmosphere which are the sources of life for all. The North is worried by the great number of people in the South, who continue to increase. These large numbers, if multiplied by increased consumption and industrialization, will be a main factor in tomorrow’s world environment. The North, therefore, appeals to the South not to repeat the mistake it has made when it industrialized and developed.”<sup>9</sup>

17. But the statements so far considered are very much in the realm of generalities. The global position on the population situation can certainly be stated more concretely. The United Nations estimates for the half-centuries prior to 1950 suggests that by 1750, the world had a total population of approximately 791 million, of which 201 million were in the more developed and 590 million in the less developed regions. By the beginning of the present century, the total population of the world was estimated at 1,650 million, with 573 million in the more developed parts of the world and 1,077 million in the less developed regions.<sup>10</sup> Table 1 summarizes the global position of the world’s total population, the share of the more and less developed regions and the respective annual rates of increase.

TABLE 1. WORLD POPULATION BY DECADES, 1900-1970

Year	Population (millions)			Annual rates of increase (percentage)		
	World total	More developed regions	Less developed regions	World total	More developed regions	Less developed regions
1900	1,650	573	1,077	...	...	...
1910	1,775	650	1,125	0.7	1.3	0.4
1920	1,837	682	1,155	0.3	0.5	0.3
1930	2,044	759	1,285	1.1	1.1	1.1
1940	2,267	821	1,446	1.0	0.8	1.2
1950	2,506	857	1,649	0.9	0.4	1.2
1960	2,995	976	2,019	1.8	1.3	2.1
1970	3,621	1,084	2,537	1.9	1.1	2.3

SOURCE: United Nations Secretariat, Population Division, “Demographic trends in the world and its major regions, 1950-1970”, *Population Debate*, vol. 1, part two, table 1.

18. Between 1950 and 1970, it is estimated that the world population increased by 44 per cent. In the more developed parts of the world, the increase amounted to 26 per cent, while in the less developed regions of the world the population rose by 54 per cent. A breakdown by major areas show that the increase in Europe was by 17 per cent, in the Union of Soviet Socialist Republics by 35 per cent, in North America by 36 per cent and in East Asia by 38 per cent. In the less developed regions of the world, Africa increased its

population by 60 per cent, South Asia by 59 per cent and Latin America by 73 per cent. The last-named three areas of the world and Oceania accounted for 43.6 per cent of the total world population in 1950 as against 48.8 per cent in 1970.<sup>11</sup>

19. Available evidence suggests that the remaining period of the present century will continue to experience accelerated growth in world population. More recent

<sup>11</sup> *Ibid.*, para. 8.

estimates of the demographic prospects by the United Nations suggests that between 1970 and the year 2000, the world population may rise from 3,621 million to 6,407 million. Of the totals indicated, the share of the less developed regions of the world is expected to rise from about 2,537 million in 1970 to 5,039 million by the year 2000. The annual rates of growth in the less developed regions is expected to decrease only slightly from 2.4 per cent in 1970 to 2.1 per cent in the year 2000 as against 0.9 per cent for 1970 and 0.6 per cent in the developed regions by the end of the century.<sup>12</sup>

20. Assuming that fertility in every major area of the world will eventually be reduced to the replacement level during the twenty-first century, the more developed parts of the world will, on the basis of United Nations medium variant assumption, stabilize at about 1.9 thousand million. That of the less developed regions is expected to grow up to 10.5 thousand million by the year 2125. Available evidence thus points to a continued widening gap in the size of population of the developed and less developed areas of the world beyond the year 2000.<sup>13</sup>

21. The accelerated growth rate of the world population may be alternatively assessed by considering the doubling-time. Information available suggests that between 1650 and 1750, the doubling-time of the world population was approximately 231 years. Between 1850 and 1900, the annual growth rate had reduced the doubling-time to 116 years. From 1930 to 1940, with an estimated growth rate of 1 per cent per annum, the doubling-time was approximately 69 years. By 1960, the time had been reduced to about 38 years. The current doubling-time for the global population is between 30 and 35 years.<sup>14</sup> In the case of developing countries, the

doubling-time in 1950 was about 58 years and in 1960, 34 years. By 1970, the population of the developing regions of the world was doubling every 30 years.

22. However, analysis of global momentum of population growth must be considered against the background of country changes. The growth incidence has been far from uniform. Accelerated growth rates were first encountered in those countries which earlier experienced the process of modernization. These changes included revolutions in agricultural techniques, commerce, industry, science and technology. The basis of the modern economy of affluent societies began earlier in Europe and America and did not have a decisive impact on the remaining two thirds of mankind in Asia, Latin America and Africa until after the Second World War.<sup>15</sup>

23. Gunnar Myrdal has estimated that on the basis of the current two-thirds share of the total world population, the changing population trend is likely to result in a population of approximately four fifths for the developing countries by the end of the century.<sup>16</sup> He further advanced the view that by that time, the population of developed countries is expected to move towards a stationary condition, while that of developing countries is expected to grow further, possibly resulting in a total population of from 10 thousand million to 15 thousand million, and probably more. These figures, though largely estimated, underline the importance of the developing world in the growing population problem. Table 2 shows the percentage of distribution by the more developed and less developed regions and of major areas of the world, 1970-2125, on the basis of the United Nations medium-variant projection.

Europe	12.7	8.4	6.4	5.3	4.9	4.8	4.8
Oceania	0.5	0.5	0.5	0.4	0.4	0.4	0.4
USSR	6.7	5.0	4.1	3.5	3.3	3.2	3.2

SOURCE: United Nations Secretariat, Population Division, "World and regional population prospects", *Population Debate*, vol. I, part two, table 9.

24. A closer study of the changing trends in human numbers indicates that in what are now the more developed parts of the world, accelerated growth was a feature of the nineteenth century. The more recent years have shown a slowing-down. However, in the less developed parts of the world, a combination of high death rate and disruptive events kept the rate of population increase at a low level in the last century. The sharp upward trend in developing countries dates back to the early 1950s. In these regions, the dramatic impact of accumulated medical discoveries and public health measures was very much delayed by the economic conditions and wars until after 1945. Death rates have been reduced more rapidly, while birth rates have changed little.<sup>17</sup>

25. Future prospects according to the United Nations medium-variant projection suggests that the approximate doubling-time of the population in Europe will rise from about 100 years in the period 1970-1975 to 116 years in the period between 1995 and the year 2000 (table 3). Similarly, in North America, the doubling-time will increase from 54 years in 1970-1975 to 70 years in 1995-2000, while that of the USSR will change from 70 years to 88 years over the same period. East Asia will rise from 41 years to 63 years during the same span.

TABLE 3. POPULATION PROSPECTS: APPROXIMATE DOUBLING-TIME PERIOD, BY REGION, 1970-2000

Region	(Years)		
	1970-1975	1980-1985	1995-2000
East Asia	41	47	63
South Asia	25	25	35
Europe	100	100	116
USSR	70	58	88
Africa	25	23	25

Latin America	24	25	25
Oceania	33	32	44
World	35	35	41

26. Among the least developed regions of the world, South Asia will experience a change in the doubling-time from 25 years in 1970-1975 to 35 years in 1995-2000, while the time span in Africa and Latin America will remain about 25 years. Over the same period, the doubling-time of the world population will change from 35 years in 1970-1975 to 41 years over the period 1995-2000.

27. However, conditions within the two less developed regions, Africa and Latin America, differ considerably. United Nations medium-variant projections indicate that between 1970 and 1975 the doubling-time for the major Africa regions ranged from 22 years

in Northern Africa to 26 years in Western and Eastern Africa. Middle Africa and Southern Africa were doubling their populations in 29 and 28 years, respectively. In Latin America, Tropical South America and Middle America were doubling their populations in 23 years and 21 years, while the Caribbean, with a doubling-time of 32 years, was also increasing its population rapidly. In Temperate South America, the doubling time was 41 years.

28. For the period 1995 to 2000, the doubling-time of most of the major regions of Africa is expected to range from about 24 to 28 years. Western Africa and Middle Africa will be doubling their populations every 25 years, while the populations of Eastern Africa and Northern Africa will be doubling every 24 and 26 years, respectively. In Southern Africa, the doubling is expected to remain the same at 28 years. The high rate of population growth characteristic of Africa will also be experienced in Latin America, where the doubling-time for most of the regions, excluding Temperate South America, will still be between 23 and 33 years. It is only in Temperate South America that an improvement to 50 years is expected by the period 1995-2000.

29. However, even the regional and subregional growth rates conceal major differences among countries and within countries. Recent census results in East Africa suggest growth rates well in excess of the average given by the medium-variant projection. In 1969, the Uganda census adjusted for immigration suggested a natural rate of increase of 3.2 per cent at the end of the 1959-1969 decade.<sup>18</sup> Analysis for the United Republic of Tanzania similarly suggests a growth rate in excess of 3.0 per cent per annum by 1980.<sup>19</sup> In Kenya, the 1962 census indicated that the African population was increasing at the rate of 3.0 per cent per annum. The census in August 1969 indicated a national growth rate of 3.3 per cent per annum and a rate for the African population estimated at 3.5 per cent per annum.<sup>20</sup> Analysis of the major ethnic groups in Kenya indicated rates far in excess of the average of 3.5 per cent for the African population. It is increases of the above-cited nature that strengthens the forecast of continued acceleration of population growth of the less developed countries well into the twenty-first century.

30. This paper has so far dealt with the rate of population growth primarily because it is one of the most often discussed aspects by those who propose a drastic reduction of fertility as a measure of control of the population inflation. However, there are other

features of population change which are aggravated by the high rate of population growth. The most important of these are structural changes and spatial redistribution of population.

31. Among the most significant changes has been the age composition, which greatly affects social and economic activities. In the more developed parts of the world, the proportion of persons aged 0-14 years has shown a marked decrease since 1950, while in the developing countries there has been an increase.<sup>21</sup> Table 4 summarizes the changes that have been experienced by the three main functional groups. In developing countries of the world, future years will witness a sharp rise in the proportion of dependent population in response to sustained fertility and falling

<sup>21</sup> United Nations Secretariat, Population Division, "Demographic trends in the world and its major regions, 1950-1970", *loc. cit.*, table 8.

mortality rates. These changes will be accompanied by increasing pressure on world opportunities, social facilities and services.

32. Among the most important changes in the population of developing countries is spatial redistribution and in particular the accelerating tempo of urbanization. Urbanization has been described as the crisis problem of the 1970s.<sup>22</sup> In the affluent parts of the world, the tendency has been to describe urbanization as mankind's environmental disruption, while among the developing countries it has been considered within the context of underdevelopment. The first attention of the United Nations Development Decade was very much directed to the underdevelopment aspect of urbanization leading to deterioration of urban areas. In the Second Develop-

<sup>a</sup> More developed region.

ment Decade, concern with urbanization as an increasing characteristic of world population change has received a further impetus. This increasing attention on the characteristic trends is largely stimulated by the nature of urban growth rate at the global regional and national levels.

33. In 1950, the annual rate of growth of the urban population in the world was 3.4 per cent (table 5). By

the year 2000 it is expected to fall slightly to 2.8 per cent. In the more developed parts of the world, the rate of urbanization is expected to decline from 2.8 per cent during the decade 1950-1960 to 1.4 per cent in the period 1990-2000. However, in the less developed parts of the world, the annual rate of urbanization is expected to rise from 4.3 per cent in the decade 1950-1960 to 4.6 per cent in 1960-1970.

TABLE 5. ANNUAL RATES OF GROWTH IN URBAN POPULATION, 1950-2000  
(Percentage)

Region	1950-1960	1960-1970	1970-1980	1980-1990	1990-2000
World total	3.4	3.2	3.2	3.1	2.8

SOURCE: "Urban and rural population: individual countries, 1950-1985, and regions and major areas, 1950-2000" (ESA/P/WP.33/Rev.1), table 3.

34. By the year 2000, the rate is expected to decline to just under 4 per cent per annum.<sup>23</sup> Very high rates of urbanization are expected in Africa, Latin America and East and South Asia. In Africa, the annual rate of urban growth is expected to rise from 4.7 per cent during the 1950-1960 decade to 5.0 per cent over the 1970-1980 period. By the year 2000, the rate will be slightly less than 5 per cent per annum. The decreasing tempo of urbanization in the more developed continents is underlined by the fact that in Europe the decline is expected to be from 1.7 per cent to 1.2 per cent whereas in North America it will be from 2.7 to 1.5 per cent for the two decades.<sup>24</sup> Over the same period, the proportion of total urban population will rise from 28.3 per cent in 1950 to 51.1 per cent in the year 2000. Comparable figures suggest a rise of from 51.2 per cent in 1950 to 80.7 per cent in the year 2000 for the more developed regions of the world.

35. In the less developed parts of the world, the proportion of urban population will rise from a modest level of 16.3 per cent in 1950 to 42.6 per cent in the year 2000. This will represent an estimated increase of total urban population from 265 million in 1950 to 2,155 million by the year 2000 (table 6). Estimates for individual regions suggest that the urban proportion in East Asia will rise from 15.9 per cent to 50.7 per cent, South Asia from 15.9 per cent to 33.7 per cent, Africa

14.0 per cent to 39.2 per cent and Latin America 40.5 per cent to 75.9 per cent between 1950 and the year

<sup>23</sup> "Urban and rural population: individual countries, 1950-1985 and regions and major areas, 1950-2000" (ESA/P/WP.33/Rev.1), table 3.

<sup>24</sup> *Ibid.*

2000.<sup>25</sup> In the 30-year period from 1970 to 2000, the total urban population of the less developed regions of the world is expected to increase more than threefold. Clearly, the need for houses, power systems, sanitation, schools, transport and other costly urban infrastructure will have to be expanded in relation to the pressure that is certain to develop.

36. Some of the most acute environmental conditions in developing countries arise from the growing tendency of urban population to concentrate in a few large cities. By 1960, it is estimated that 68 per cent of the total population in localities of 20,000 inhabitants or more were living in cities of 100,000 or more. Table 7 shows the extent to which the world's urban population is concentrated in cities with 1 million or more inhabitants. By 1950, there were 75 cities having at least 1 million inhabitants.<sup>26</sup> These constituted about a third of the world total. In 1970, the number of such cities in developing countries constituted a little less than a half of the total for the world as a whole. During the same interval the combined population of the "million-cities" increased from 174 million to 416 million. In the more developed regions, the increase was from 126 million to 223 million. However, in the less developed regions, the increase was from 48 million to 193 million. The concentration of population in the "million-cities" has therefore been a more marked characteristic of the developing regions of the world.<sup>27</sup>

37. Between 1950 and 1985, the annual compound growth rate for the old and new "million-cities" combined in the more developed regions is estimated at 2.9 per cent as against 6.7 per cent in the less developed regions. Estimated growth rates of 5.4 and 7.1 per cent

for East Asia and South Asia respectively, 9.3 per cent for Africa and 6.1 per cent for Latin America underline the problem of the large city growth in developing regions of the world in the Second United Nations Development Decade.<sup>28</sup>

38. Over the same period, the population of the "million-cities" in East Asia is expected to increase from 31.4 million to 195.2 million, in South Asia from 15.0 million to 165.8 million, in Africa from 3.4 million to 46.8 million and in Latin America from 15.3 million to 120.8 million.

39. But total figures for individual continents and countries conceal the acute problems associated with the phenomenal growth of individual cities. In India, the cities of Calcutta and Bombay, which in 1950 had populations of 4.1 million and 2.7 million, respectively, by 1970 had reached 6.9 million and 5.8 million each. In 1985, the two giant cities are expected to top the 12 million mark each. Delhi, which in 1950 had 1.3 million, is expected to have a population of 3.5 million in 1970 and 8.5 million in 1985.<sup>29</sup>

40. In Africa, between 1970 and 1985, Lagos is expected to increase its population almost fivefold, Ibadan threefold, Accra twofold, and Addis Ababa, Nairobi and Kinshasa threefold. In Northern Africa, Casablanca and Algiers are expected to double their populations. In Southern Africa, Johannesburg, Cape Town and Durban, which had reached the million threshold by 1970, are also expected at least to double their populations.

41. In Latin America, the giant cities of São Paulo and Rio de Janeiro are expected to increase their populations from 7.8 million and 6.8 million each to 16.8 million and 11.4 million, respectively, by 1985. Lima-

Callao in Peru will double its population between 1970 and 1985. Mexico, with a population of 2.9 million in 1950, is expected to double its population from 8.3 million in 1970 to 17.9 million in 1985.

#### ENVIRONMENTAL CONSEQUENCES OF POPULATION GROWTH IN DEVELOPING COUNTRIES

42. The fact that the unprecedented rapid population increase in developing countries, which is going on and may well proceed for decades and certainly for more than a generation, places a heavy impediment in the way of development needs no emphasis. Population increase is the vital factor in environmental problems. Natural resources have to be considered in relation to the size of the population which has to be provided for. Pollution in its various forms in the rural and urban areas is clearly a function of density of population. Developing countries are thus caught up in the dilemma of lack of development and adverse effects of modern development. The Prime Minister of India, addressing the plenary session of the United Nations Conference on the Human Environment in Stockholm, had this to say:

“Are not poverty and need the greatest polluters? For instance, unless we are in a position to provide employment and purchasing power for the daily necessities of the tribal people and those who live in or around our jungles, we cannot prevent them from combing the forest for food and livelihood; from poaching and from despoiling vegetation . . . . The environment cannot be improved in conditions of poverty. Nor can poverty be eradicated without the use of science and technology.”<sup>30</sup>

43. Among the areas that are hit hardest are the social services, such as health and education. The Director-General of the World Health Organization, in addressing the Human Environment Conference, warned of “the dangers created by polluted drinking water and low levels of housing and sanitation” in developing countries. He estimated that 80 per cent of the world population is faced with these kinds of problems rather than with the consequence of industrialization.

44. Food production is a field in which the developing countries are particularly vulnerable. Technology in these areas is either lacking or is insufficiently developed to protect the population from the vagaries of the physical environment. Whether it is the exceptional drought or the excesses of floods, the periodic crises which face millions of people in the less developed parts of the world are a serious reminder of the dangers of uncontrolled population growth. The observation of the Director-General of the Food and Agriculture Organization of the United Nations is worth recalling:

“There will be twice as many people on our planet in the year 2000, twice as many mouths to feed.

<sup>30</sup> Indira Ghandi, “Life is one and the world is one”, in *Environment Stockholm* (United Nations publication, Geneva, 1972), p. 18.

Most of this increase will occur in the developing, already under-nourished and over-populated parts of the world. To meet their requirements, agricultural production should be doubled every 18 years—a rate never achieved over a sustained period by the countries that are now well fed.”<sup>31</sup>

45. Lack of education is an indirect factor in environmental deterioration. Many well-conceived programmes of development have foundered on the rock of ignorance. In this respect, it is important to note that with increasing population and inability of Governments to provide for more than a bare minimum, the problem of illiteracy will be on the increase. Education is central to development and the consequence of education being scarce in the face of environmental challenges is already a fundamental issue in developing countries.

46. The rural populations of developing countries are among the most poorly housed. Most countries have concentrated on housing policies that favour the urban dwellers. However, in countries of the world where well over 80 per cent of the population live in rural areas, the problem of providing a decent shelter for the rural population is a crisis that cannot be ignored by development programmes. Accelerated population growth, particularly of rural populations, will intensify the difficulties of developing countries in achieving the objectives of improved rural housing.

47. The problems considered so far are those which arise from the lack of development in developing countries. They are the problems that afflict those parts of the world where lack of capital resources continue to hamper development and where the trained manpower gap constitutes a real bottle-neck to implementation of development programmes. However, those problems arising from existing development policies which are responsible for serious environmental problems are now considered. These problems arise from the nature of agricultural transformation in developing countries, industrialization including the basic problem of location and the rural-urban exodus.

48. While industrialization remains the goal of developing countries of the world, the development of agriculture, the mainstay of the vast majority of the population, remains a major priority area. However, lack of agricultural jobs means that the gap between the demand for jobs and employment opportunities is very wide. With increasing population it means that labour in the agricultural sector is frequently underemployed. At times of drought, the entire labour force in agriculture may be idle.

49. Agriculture in developing countries faces the twin demand for creating more gainful employment and preventing a decrease in *per capita* income and hence increasing poverty. With an increasing density of popu-

<sup>31</sup> “If we do not accept hunger . . .”, speech by the Director-General of the Food and Agriculture Organization of the United Nations to the United Nations Conference on the Human Environment, Stockholm, June 1972, in *Environment Stockholm, loc. cit.*, p. 18.

lation, these problems become more intractable. The objective of agriculture must be to sustain a high employment target. But opportunities must also be found to absorb the increasing population by finding work opportunities outside agriculture.

50. However, the most obvious problem of environmental impact arises from the effort to raise productivity in response to new demands on agriculture through the application of technology. There are such new hazards as the application of chemical weed control and the increasing use of insecticides whose environmental impacts have not been adequately studied. For some time, the application of irrigation technology has been advocated as a means to fuller utilization of available agricultural potential. On the other hand, it is becoming clear that for irrigation technology to pay, there is a minimum below which productivity cannot fall. Even the "green revolution" does not appear to have provided the solution to the problem of increasing work opportunities on the land.

51. Industrialization enjoys a high priority as a means to counteracting the persistent poverty and lack of development that prevails in developing countries. However, there are problems of industrial location to be considered. Some developing countries that are hard-pressed by population problems have been prone to accept industrialization which more developed countries are in the process of correcting. The danger is that faced with the urgency of providing employment opportunities for the rising labour force, developing countries may fail to apply the safeguards essential for preservation of the quality of the environment.

52. Analysis of the global, regional and national context of the problem of urban explosion in developing countries underlines the dangers of environmental disruption and an undesirable effect on human living. The unplanned urban growth and associated sanitary problems, the increasing difficulties being experienced in providing houses and other essential urban facilities are now well known among development planners in the less developed parts of the world. It has been stressed that these problems will intensify in response to the pattern of growth outlined. However, the concentration on the physical aspects of environmental disruption tends to minimize the psycho-social impact of the new, phenomenal urban growth. The need to adjust the totally new and at times unintegrated communities underlies some mental maladjustment that is now attracting the attention of health authorities.

#### POSSIBILITIES THAT TECHNOLOGY OFFERS

53. Developing countries of the world see in urbanization an instrument for spreading development to other less developed parts of the national territory. It is for this reason that urban centres as growth poles figure prominently in the physical development plans of some countries. But the concept of growth poles is

based on the view that urbanization in an essential condition for reducing the poverty gap between regions and among the various sections of the national community. It is based on the conviction that planned use of modern technology can mitigate the undesirable aspects of urbanization trends in the developing world. Planning technology is based on the conviction that an alternative settlement pattern is a feasible solution to environmental deterioration.

54. However, the concentration on the urban aspects of population change may lead to an undue emphasis on the urban end of the population problem. The spread of urban development is certainly a means of bringing technology to serve a rural community previously denied access to the urban services. However, some decisive action must be taken to arrest the excessive rates of population growth.

55. The traditional approach to the problem advocated had been to attack the biological causes of the population explosion through a widespread adoption of contraceptives. However, as Barry Commoner has argued, such an approach has failed to bring about a significant reduction in human fertility in the less developed regions of the world.<sup>32</sup> The general conclusion is that the desired demographic transition which is conducive to improved living conditions and to the preservation of environmental quality requires a far more complex approach and the application of technology which would influence peoples' choice of families. However, implicit in the analysis of the paper is the view that the developing countries are faced by a problem that is already there and by the prospects of further deterioration in the situation in the near future.

56. The technology of fertility control which has enabled the more developed parts of the world to devote increasing resources to development needs is clearly there. It must be made available to the population of developing regions as an inseparable part of the development strategy in the current state of the demographic evolution of the regions concerned. But it is essential that there be a determined attack on the sociological factors that underlie the continuing preference for large families, especially the desire for survival and security in old age.

57. Problems of poverty and lack of development are far more complex. Their solution in the more developed parts of the world has involved not merely the application of technology, but in a very specific way the overhaul of the institutional framework. The state of environmental deterioration and persistent lack of development has a human dimension and it is the capacity of the institutional framework to adapt to available technology that will determine the success of remedial measures whether applied globally, regionally or nationally.

<sup>32</sup> Barry Commoner, "Survival in the environmental population crisis", in S. F. Singer, ed., *Is There an Optimum Level of Population?* (New York, McGraw Hill, 1971), pp. 96-113.

## HUMAN POPULATION AND THE GLOBAL ENVIRONMENT\*

Paul R. Ehrlich\*\* and John P. Holdren\*\*\*

1. Three dangerous fallacies appear to be widespread among decision-makers and others with responsibilities related to population growth, environmental deterioration and resource depletion. The first is that the absolute size and rate of growth of the human population has little or no relationship to the rapidly escalating ecological problems facing mankind. The second is that environmental deterioration consists primarily of "pollution", which is perceived as a local and reversible phenomenon of concern mainly for its obvious and immediate effects on human health. The third fallacy is that science and technology can overcome all problems arising from the scale and rate of growth of consumption of natural resources.

2. The authors, and many others, have dealt at length with the third fallacy elsewhere.<sup>1</sup> This paper demonstrates that population size and the rate of population growth, in both developed and developing countries, are important factors in producing environmental deterioration. Further, it is asserted that such deterioration is a much more subtle, pervasive and dangerous phenomenon than is implied by the simplistic view of "pollution" alluded to above.<sup>2</sup>

3. Environmental problems can be classified according to the nature of the damage to human beings, as follows:

(a) Direct assaults on human welfare, including obvious damage to health (for example, lead poisoning

or aggravation of lung disease by air pollution); damage to goods and services (for example, the corrosive effects of air pollution on buildings and crops); social disruption (for example, displacement of people from their living areas by mining operations and hydroelectric projects); and other direct effects on what people perceive as their "quality of life" (for example, congestion, noise and litter);

(b) Indirect effects on human welfare through interference with services provided for society by natural biological systems (for example, diminution of ocean productivity by filling estuaries and polluting coastal waters and acceleration of erosion by logging or overgrazing).

4. Most of the attention devoted to environmental matters by scientists, politicians and the public has been focused on the direct effects and, more particularly, on their acute rather than their chronic manifestations. This is only natural. It would be wrong, however, to interpret limited legislative and technical progress towards ameliorating the direct, acute symptoms of environmental damage as evidence that society is on its way to an orderly resolution of its environmental problems. The problem is not merely that the discovery, implementation and enforcement of treatment for those obvious symptoms is likely to be expensive and difficult. Unfortunately, the long-term human consequences of chronic exposure to low concentrations of environmental contaminants may be more serious—and the causes less amenable to detection and removal—than those of acute pollution as it is perceived today.

5. The most serious threats of all, however, may well prove to be the indirect ones generated by mankind's disruption of the functioning of the natural environment—the second category listed above, which is now discussed. The topic is developed in the following steps. First, the relevance of environmental disruption to human welfare is established by examining the services provided for society by nature. Then, some historical examples of ecological disruption caused by human activities are given, followed by an examination of the role of contemporary civilization as an ecological force. Against this background, the role of demographic variables—population size, growth rate and geographical distribution—in generating ecological problems is considered. A discussion of time factors relevant to ecological problems emphasizes growth rates, sources of momentum in the factors generating the problems, the

possibility of irreversible environmental damage and the issue of imminence—the reasons for believing that serious ecological impact on the welfare of civilization will be felt sooner rather than later.

#### NATURAL RESOURCES

6. The most obvious services provided for humanity by the natural environment have to do with food production. The fertility of the soil is maintained by the plants, animals and micro-organisms that participate in the great nutrient cycles—nitrogen, phosphorus, carbon and sulphur. Soil itself is produced from plant debris and weathered rock by the joint action of bacteria, fungi, worms, soil mites and insects. The best protection against erosion of soil and flooding is natural vegetation.

7. At many stages of the natural processes comprising the nutrient cycles, organisms accomplish what humans have not yet learned to do—the complete conversion of wastes into resources, with solar energy captured by photosynthesis as the driving energy source. Human society depends upon these natural processes to recycle many of its own wastes, from sewage to detergent to industrial effluents. (Reflect on the term “biodegradable”.) In the course of the same cycles, the atmospheric concentrations of ammonia, carbon monoxide and hydrogen sulphide—all poisonous—are biologically controlled.<sup>3</sup>

8. Insects pollinate most vegetables, fruits and berries. Most fish—the source of from 10 to 15 per cent of the animal protein consumed by mankind<sup>4</sup>—are produced in the natural marine environment, unregulated by man. (As is well known, animal protein is the nutrient in shortest supply in a chronically undernourished world.) Most potential crop pests—one competent estimate is 99 per cent—are held in check not by man, but by their natural enemies and by characteristics of the physical environment, such as temperature, moisture and availability of breeding sites.<sup>5</sup> Similarly, some agents of human disease are controlled principally not by medical technology, but by environmental conditions; and some carriers of such agents are controlled by a combination of environmental conditions and natural enemies.<sup>6</sup>

9. Lastly, the natural environment in its diversity can be viewed as a unique library of genetic information. New food crops, new drugs and vaccines and new bio-

logical pest controls can be drawn from this library. The loss of a species, or even a loss of genetic diversity within a species, is the loss forever of a potential opportunity to improve human welfare.

10. These “public-service” functions of the global environment cannot be replaced by technology now or in the foreseeable future. In some cases, this is so because the process by which the service is provided is not understood scientifically and in other cases, because no technological equivalent for the natural process has yet been devised. But in the largest number of cases, the sheer size of the tasks simply dwarfs civilization’s capacity to finance, produce and deploy new technology. The day is far away when food for billions will be grown on synthetic nutrients in greenhouses free of pests and plant diseases, when the wastes of civilization will be recycled entirely by technological means and when all mankind will live in surroundings as sterile and as thoroughly managed as those of an Apollo space capsule. Until that improbable future arrives—and it may never come—the services provided by the orderly operation of natural biological processes will continue to be irreplaceable as well as indispensable.

#### HISTORY OF HUMAN ECOLOGICAL DISRUPTION

11. Ecological disruption on a large scale by human beings is not a new phenomenon. Even before the advent of agriculture, man as a hunter is thought to have contributed to a reduction in the number of species of large mammals inhabiting the earth.<sup>7</sup> Much more significant, however, was the era of abuse of soils and habitat that was initiated by the agricultural revolution about 10,000 years ago and has continued up to the present.

12. One of the best-known early examples is the conversion to desert of the lush Tigris and Euphrates valleys, through erosion and salt accumulation resulting from faulty irrigation practices.<sup>8</sup> In essence, the downfall of the great Mesopotamian civilization appears to have been the result of an “eco-catastrophe”. Overgrazing and poor cultivation practices have contributed over the millennia to the expansion of the Great Sahara Desert, a process that continues today;<sup>9</sup> and the Rajasthan Desert in India is also believed to be in part a product of human carelessness and population pressure.<sup>10</sup>

13. Much of Europe and Asia were deforested by pre-industrial men, beginning in the Stone Age; heavy erosion, recurrent flooding and the nearly permanent loss of a valuable resource were the result.<sup>11</sup> Overgrazing by the sheep of Navajo herdsmen has destroyed large tracts of once prime pasture in the South-western area of the United States of America.<sup>12</sup> Attempts to cultivate too intensively the fragile soils of tropical rain-forest areas are suspected of being at least in part responsible for the collapse of the Mayan civilization in Central America and that of the Khmers in what is today the Khmer Republic.<sup>13</sup> (The famous temples at Angkor Wat were built in part of laterite, the rock-like material that results when certain tropical soils are exposed to the air through cultivation.)

14. The practice of agriculture—even where quality of soils, erosion or salt accumulation do not pose problems—may encounter ecological difficulties. The most basic one is that agriculture is a simplifier of ecosystems, replacing complex natural biological communities with relatively simple man-made ones based on a few strains of crops. Being less complex, agricultural communities tend to be less stable than their natural counterparts; they are vulnerable to invasions by weeds, insect pests and plant diseases, and they are particularly sensitive to extremes of weather and variations in climate. Historically, man has attempted to defend his agricultural communities against the instabilities to which they are susceptible by means of vigilance and the application of “energy subsidies”—for example, hoeing weeds and, more recently, applying pesticides and fungicides. He has not always been successful. The Irish potato famine of the nineteenth century is, perhaps, the best-known example of the collapse of a simple agricultural ecosystem. The heavy reliance of the Irish population on a single, highly productive crop led to 1.5 million deaths when the potato monoculture fell victim to a fungus.<sup>14</sup> To put it another way, the carrying capacity of Ireland was reduced, and the Irish population crashed.

#### CONTEMPORARY MAN AS AN ECOLOGICAL FORCE

##### *Agriculture*

15. Advances in agricultural technology in the past 100 years have not resolved the ecological dilemma of agriculture; they have aggravated it. The dilemma can be summarized this way: civilization tries to manage ecosystems in such a way as to maximize productivity;<sup>15</sup>

<sup>11</sup> H. C. Darby, “The clearing of the woodland in Europe”, in William L. Thomas, Jr., ed., *Man's Role in Changing the Face of the Earth* (Chicago, University of Chicago Press, 1956), p. 183.

<sup>14</sup> G. L. Carefoot and E. R. Sprott, *Famine on the Wind: Man's Battle Against Plant Disease* (Chicago, Illinois, Rand McNally, 1967).

<sup>15</sup> Readers unfamiliar with the terminology and principles

“nature” manages ecosystems in such a way as to maximize stability; and the two goals are incompatible. Ecological succession proceeds in the direction of increasing complexity. Ecological research has shown that the most complex (and stable) natural ecosystems tend to have the smallest net community productivity; less complex, transitional ecosystems have higher net community productivity; and the highest net community productivities are achieved in the artificially simplified agricultural ecosystems of man (see table 1). In short, productivity is achieved at the expense of stability.

TABLE 1. PRODUCTIVITY OF VARIOUS ECOSYSTEMS  
(Kilocalories of energy per square metre per annum)

Ecosystem	Net primary productivity	Net community productivity
Alfalfa field	15,200	14,400
Pine forest	5,000	2,000
Tropical rain-forest	13,000	Little or none
Long Island Sound	2,500	Little or none

SOURCE: Eugene P. Odum, *Fundamentals of Ecology*, 3rd ed. (Philadelphia, Saunders, 1971), p. 46.

Note: Some ecologists use grams of dry organic matter or grams of carbon in place of kilocalories. There are about 4 kilocalories of available bond energy per gram of dry organic matter, or 10 kilocalories per gram of contained carbon. The average human being metabolizes 2,500 kilocalories per day.

16. Of course, mankind would have to practise agriculture to support even a fraction of the existing human population. A tendency towards instability in agricultural ecosystems must be accepted and, where possible, compensated for by technology. However, the trends in modern agriculture—associated in part with the urgent need to cope with unprecedented population growth and in part with the desire to maximize yields per acre for strictly economic reasons—are especially worrisome ecologically. There are four major liabilities:

(a) As larger and larger land areas are given over to farming, the unexploited tracts available to serve as reservoirs of species diversity and to carry out the “public-service” functions of natural ecosystems become smaller and fewer. (World land-use patterns are summarized in table 2.);

(b) Pressure to expand the area under agriculture is leading to destructive attempts to cultivate land that is actually unsuited for cultivation with the technologies at hand. Thus, the expansion of agriculture to steep hill-sides has led to serious erosion in Indonesia,<sup>16</sup> the increasing pressure of slash-and-burn techniques is destroying tropical forests in the Philippines,<sup>17</sup> and

of ecology should read the annex before proceeding with this section.

attempts to apply the techniques of temperate-zone agriculture to the tropical soils of Brazil and southern Sudan have led to erosion, loss of nutrients and laterization.<sup>18</sup> Over-logging of tropical forests has had similar effects;

(c) Even in parts of the world where land area under agriculture is constant or (for economic reasons) dwindling, attempts to maximize yields per acre have led to dramatic increases in the use of pesticides and inorganic fertilizers, which have far-reaching ecological consequences;<sup>19</sup>

(d) The quest for high yields has led also to the replacement of a wide variety of traditional crop varieties all over the world with a few, specially bred, high-yield strains. Unprecedented areas are now planted to a single variety of wheat or rice. This enormous expansion of monoculture has increased the probability and the potential magnitude of epidemic crop failure from insects or disease.<sup>20</sup>

#### Effects of pollution on ecosystems

17. The expansion and intensification of agriculture has been accompanied by a continuing industrial revolution that has multiplied many times over both the magnitude and variety of the substances introduced into the biological environment by man. It is useful to

classify these substances as "qualitative pollutants" (synthetic substances produced and released only by man) and "quantitative pollutants" (substances naturally present in the environment, but released in significant additional quantities by man).

18. Well-known qualitative pollutants are the chlorinated hydrocarbon pesticides, such as DDT, the related class of industrial chemicals called PCBs (polychlorinated biphenyls) and some herbicides. These substances are biologically active in the sense of stimulating physiological changes; but since organisms have had no experience with them over evolutionary time, the substances are usually not easily biodegradable.<sup>21</sup> Thus, they may persist in the environment for years and decades after being introduced, and be transported around the globe by wind and water.<sup>22</sup> Their long-term effects will be discovered only by experience, but their potential for disruption of ecosystems is enormous.<sup>23</sup>

19. Within the category of quantitative pollutants, there are three criteria by which a contribution made by mankind may be judged significant:

(a) Man can perturb a natural cycle with a large amount of a substance ordinarily considered innocuous, either by overloading part of the cycle (as is done to the denitrifying part of the nitrogen cycle when one over-fertilizes, leading to the accumulation of nitrates and nitrites in ground water;<sup>24</sup> by destabilizing a finely

tuned balance (as is done to the global atmospheric heat engine, which governs global climate, by adding CO<sup>2</sup> to the atmosphere through combustion of fossil fuels<sup>25</sup>); or by swamping a natural cycle completely (as could happen to the climatic balance in the very long term from man's input of waste heat<sup>26</sup>);

(b) An amount of material negligible compared with natural global flows of the same substance can cause great damage if released in a sensitive spot, over a small area or suddenly (for example, the destruction of coral reefs in Hawaii by silt washed from construction sites);

(c) Any addition of a substance that can be harmful even at its naturally occurring concentrations must be considered significant. Some radio-active substances fall into this category, as does mercury.

20. The most general effect of pollution of all kinds on ecosystems is the loss of structure or complexity.<sup>27</sup> Specifically, food chains are shortened by pollution through the selective loss of the chief predators. This is so because compared with herbivores predators are more sensitive to environmental stresses of all kinds—pesticides, industrial effluents, thermal stress and oxygen deficiency. This increased sensitivity results from several mechanisms: the predator populations are usually smaller than those of the prey species, so the predator populations tend to have a smaller reservoir of genetic variability and, hence, less probability of evolving a resistant strain; top predators are often exposed to higher concentrations of toxic substances than organisms at lower trophic levels, owing to the phenomenon of biological concentration of pollutants as they move up the food chain; and, lastly, the direct effects of pollution on predators are compounded by the fact that pollutants may reduce the size of the prey population to the point where the predator population cannot be supported. Loss of structure may also occur at lower trophic levels when, for a variety of reasons, one species of herbivore or lower carnivore proves especially sensitive to a particular form of environmental stress. One does not have to eradicate the food web from top to bottom for significant differential effects to occur.

21. The adverse effects of loss of structure on the "public-service" functions performed by ecosystems are varied and serious. The vulnerable chief predators in marine ecosystems are generally the food fishes most highly prized by man. The loss of predators on land releases checks on herbivorous pests that compete with man for his supply of staple crops. Damaging population outbreaks of these pests—the classic "instability"—are the result. (A good example is the experience with

pesticides and cotton pests in the Canete Valley in Peru.<sup>28</sup>) The loss of structure of ecosystems also increases the load on the aquatic food webs of decay, which are already heavily stressed by the burden of mankind's domestic and agricultural wastes. The resulting overload precipitates a vicious progression: oxygen depletion; a shift from aerobic to less efficient anaerobic bacterial metabolism; the accumulation of organic matter; and the release of methane and hydrogen sulphide gas.<sup>29</sup>

#### *Vulnerability of the sea*

22. The ocean, currently indispensable as a source of animal protein, may be the most vulnerable ecosystem of all. Its vast bulk is deceiving. The great proportion of the ocean's productivity—over 99 per cent—takes place beneath 10 per cent of its surface area; and half of the productivity is concentrated in coastal upwellings amounting to only 0.1 per cent of the surface area.<sup>30</sup> The reason is that productivity requires nutrients, which are most abundant near the bottom of the sea, and sunlight, available only near the top. Only in the coastal-shelf areas and in upwellings are nutrients and sunlight both available in the same place.

23. The coastal regions, of course, also receive most of the impact of man's activities—oil spills, fall-out from atmospheric pollutants generated on the adjacent land and river out-flow bearing pesticide and fertilizer residues, heavy metals and industrial chemicals. Almost perversely, the most fertile and critical components of all in the ocean ecosystem are the estuaries into which the rivers empty; estuaries serve as residence, passage or nursery for about 90 per cent of commercially important fish.<sup>31</sup> To compound the problem of pollution, the salt-marshes that are an integral part of estuarine biological communities are being routinely destroyed by landfill operations.

24. Over-fishing is almost certainly also taking a heavy toll in the ocean, although it is difficult to separate its effect from that of pollution and destruction of the estuarine breeding grounds and nurseries. The combined result of these factors is clear, however, even if the blame cannot be accurately apportioned. Since the Second World War, the catches of the East Asian sardine, the California sardine, the North-west Pacific salmon, the Scandinavian herring and the Barents Sea cod (among others) have entered declines from which there has been no sign of recovery.<sup>32</sup>

25. Current, world fisheries production of somewhat over 60 million metric tons is already more than half

of the 100 million that some marine biologists<sup>33</sup> consider to be the maximum sustainable yield. But recent interruptions in the pattern of continuously increasing yields since the Second World War,<sup>34</sup> declining catches per unit effort and increasing international friction over fishing rights<sup>35</sup> make it seem unlikely that theoretical maximum yields will even be approached.

#### Flows of material and energy

26. Many people still imagine that mankind is a puny force in the global scale of things. They are persuaded, perhaps by the vast empty spaces visible from any jet airliner in many parts of the world, that talk of global ecological disruption is a preposterous exaggeration. The question of the absolute scale of man's impact, however, is amenable to quantitative investigation. Natural global flows of energy and materials can be reasonably calculated or estimated, providing an absolute yardstick against which to measure the impact of human activities.

27. The results are not reassuring. As a global geological and biological force, the activities of mankind are today becoming comparable to and even exceeding many natural processes. Oil added to the oceans in 1969 from tanker spills, off-shore production, routine shipping operations and refinery wastes exceeded the global input from natural seepage by an estimated twenty-fold.<sup>36</sup> The minimum estimate for 1980, assuming all foreseeable precautions, is 30 times natural seepage.<sup>37</sup> Civilization is now contributing half as much as nature to the global atmospheric sulphur burden, and will be contributing as much as nature by the year 2000.<sup>38</sup> In industrial areas, civilization's input of sulphur (as sulphur dioxide) so overwhelms natural removal processes that increased atmospheric concentrations and acidic surface-water are found from hundreds to thousands of kilometres down wind.<sup>39</sup> Combustion of fossil fuels has increased the global atmospheric concentration of carbon dioxide by 10 per cent since the turn of the century.<sup>40</sup> Civilization's contribution to the global atmospheric burden of particulate matter is uncertain; estimates range from 5 to 45 per cent of total annual input.<sup>41</sup> Roughly 5 per cent of all the energy captured by photosynthesis on earth flows

through the agricultural ecosystems supporting the metabolic consumption of human beings and their domestic animals—a few out of some millions of species.<sup>42</sup> The rates at which mankind is mobilizing critical nutrients and many metals (including the most toxic ones) considerably exceeds the basic geological mobilization rates as estimated from river flows<sup>43</sup> (see table 3). Such figures as these do not prove that disaster is imminent; but, combined with the ecological perspective summarized above, they are cause for uneasiness. In terms of the scale of its disruptions, mankind is, for the first time, operating on a level at which global balances could hinge on human mistakes.

TABLE 3. MANKIND'S MOBILIZATION OF MATERIALS  
(Thousands of metric tons per annum)

Element	Geological rate (river flow)	Man's rate (mining and consumption)
Iron	25,000	319,000
Nitrogen	3,500	19,800
Copper	375	4,460
Zinc	370	3,930
Nickel	300	358
Lead	180	2,330
Phosphorus	180	6,500
Mercury	3	7
Tin	1.5	166

SOURCE: *Man's Impact on the Global Environment: Assessment and Recommendations for Action*, report of the Study of Critical Environmental Problems (Cambridge, Mass., Massachusetts Institute of Technology Press, 1970).

28. Some of the forms of disruption described above are, of course, amenable in principle to elimination or drastic reduction through changes in technology. Discharges of oil, sulphur dioxide and carbon dioxide, for example, could be greatly reduced by switching to energy sources other than fossil fuels. In the case of these pollutants, then, the questions involve not whether the disruptions can be managed, but whether they will be; whether the measures will come in time; and what social, economic and new environmental penalties will accompany those measures. At least one environmental problem is intractable in a more absolute sense, however, and that is the discharge of waste heat accompanying all of civilization's use of energy. What is referred to here is not simply the well-publicized thermal pollution at the sites of electric generating plants, but to the fact that all the energy used—as well as that wasted in generating electricity—ultimately arrives in the environment as waste heat. This phenomenon may be understood qualitatively by considering the heat from a light-bulb, the heat from a running motor-car engine and the heat in the exhaust, the heat from friction of tyres against pavement and metal against air or the heat

from the oxidation of iron to rust—to name a few examples. Quantitatively, the ultimate conversion of all the energy used to heat (most of this occurring near the point of use and almost immediately) is required by the laws of thermodynamics; the phenomenon cannot be averted by technological tricks.

29. The usual concern with local thermal pollution at power-plants is that the waste heat, which is usually discharged in to water, will adversely affect aquatic life. By contrast, most of the waste heat from civilization's energy use as a whole is discharged directly into the atmosphere, and the concern is disruption of climate. Again, it is instructive to compare the scale of human activities with that of the corresponding natural processes, in this case the natural energy flows that govern climate. One finds that the heat production resulting from (and numerically equal to) civilization's use of energy is not yet a significant fraction of the solar energy incident at the earth's surface on a global average basis (see table 4); even if the current 5 per cent per annum rate of increase of global energy use persists, it will take another century before civilization is discharging heat equivalent to 1 per cent of incident solar energy at the surface world-wide.<sup>44</sup>

Sellers, *Physical Climatology* (Chicago, University of Chicago Press, 1965), p. 67.

30. Considerably sooner, however, as indicated in table 4, mankind's heat production could become a significant fraction of smaller natural energy transfers that play a major role in the determination of regional and continental climate (e.g., the kinetic energy of winds and ocean currents, and the poleward heat fluxes). It is especially important in this connexion that civilization's heat production is, and will continue to be, very unevenly distributed geographically. Human heat-production already exceeds 5 per cent of incident solar radiation at the surface over local areas of tens of thousands of square kilometres, and will exceed this level over areas of millions of square kilometres by the year 2000, if current trends persist.<sup>45</sup> Such figures could imply substantial climatic disruptions. In addition to the

effects of its discharge of heat, civilization has the potential to disrupt climate through its additions of carbon dioxide and particulate matter to the atmosphere, through large-scale alteration of the heat-transfer and moisture-transfer properties of the surface (e.g., agriculture, oil films on the ocean and urbanization), through cloud formation arising from aircraft contrails, and, of course, through the combined action of several or all of these disruptions.

31. Much uncertainty exists concerning the character and imminence of inadvertent climate modification through these various possibilities. It is known that a global warming of a few degrees Centigrade would melt the ice-caps and raise the sea level by 50 metres, submerging coastal plains and cities. A few degrees in the opposite direction would initiate a new ice-age. Although such global warming or cooling is certainly possible in principle, a more complicated alteration of climatic patterns seems a more probable and perhaps more imminent consequence of the very unevenly distributed impacts of civilization's use of energy. It is particularly important to note that the consequences of climatic alteration reside not in any direct sensitivity of humans to moderate changes in temperature or moisture, but rather in the great sensitivity of food production to such changes<sup>46</sup> and, perhaps, in the possible climate-related spread of diseases to populations with no resistance to them.<sup>47</sup>

32. The effect of climate on agriculture was once again being dramatically demonstrated in early 1973. Because of "bad weather", famine was widespread in sub-Saharan Africa, and was beginning in India. South East Asia had small rice harvests, parts of Latin America were short of food and crops were threatened in the Union of Soviet Socialist Republics and in the United States of America.<sup>48</sup> Another year of monsoon failure in the tropics and inclement weather in the temperate zones, and the human death rate will climb precipitously. Over-population is dramatically demonstrated in mankind's inability to store sufficient carry-over food-supplies in anticipation of the climatic events which are a regular feature of the earth.

#### THE ROLE OF POPULATION

33. This section takes up the most critical aspect of the problem with respect to the current World Population Conference: the way in which and the extent to which population variables contribute to ecological problems.

<sup>46</sup> Sherwood B. Idso, "Potential effects of global temperature change on agriculture", in W. H. Matthews, F. E. Smith and E. D. Goldberg, *Man's Impact on Terrestrial and Oceanic Ecosystems* (Cambridge, Mass., Massachusetts Institute of Technology Press, 1971), p. 184.

<sup>47</sup> Jacques M. May, *loc. cit.*, p. 184.

<sup>48</sup> The situation is serious enough to attract considerable attention in the media. See, for instance, "United Nations signals red alert for possible famine in 28 countries", *Palo Alto Times*, 8 June 1973, p. 25.

<sup>45</sup> *Inadvertent Climate Modification, loc. cit.*, pp. 55-60.

### Multiplicative effect

34. The most elementary relation between population and environmental deterioration is that population size acts as a multiplier of the activities, consumption and attendant environmental damages associated with each individual in the population. The contributing factors in at least some kinds of environmental problems can be usefully studied by expressing the population/environment relation as an equation: environmental disruption = population  $\times$  consumption per person  $\times$  damage per unit of consumption.<sup>49</sup>

35. Since the consumption of goods or services per person is a measure of affluence, and since environmental damage per unit of goods or services consumed depends in part upon the character of the technology used, the foregoing equation has sometimes been abbreviated as "pollution equals population times affluence times technology". Needless to say, the numerical quantities that appear in such an equation will vary greatly, depending upon the problem under scrutiny. Different forms of consumption and technology are relevant to each of the many forms of environmental disruption. The population factor may refer to the population of a city, a region, a country or the world, depending upon the problem being considered. (This point, of course, raises the issue of population distribution.) The equation, therefore, represents not one calculation, but many.

36. For problems described by multiplicative relations like the one just given, no factor can be considered unimportant. The consequences of the growth of each factor are amplified in proportion to the size and rate of growth of each of the other factors. Rising consumption per person has greater impact in a large population than in a small one—and greater impact in a growing population than in a stationary one. A given environmentally disruptive technology, such as the petrol-powered motor-car, is more damaging in a large, rich population (many people own motor-cars and drive them often) than in a small, poor country (few people own motor-cars, and those who do drive them less). A given level of total consumption (population times consumption per person) is more damaging if it is provided by means of a disruptive technology, such as persistent pesticides, than if provided by means of a relatively non-disruptive one, such as integrated pest control.

37. Quantitatively, the important point is that when slowly growing factors multiply each other, they lead to rapidly growing products. Consider the following example in which there are two multiplicative factors rather than three. Suppose one wishes to know whether population growth or rising consumption *per capita* played a greater role in the growth of total energy consumption in the United States of America between 1880

and 1966. In this period, total energy consumption increased about twelvefold, and the population increased fourfold.<sup>50</sup> It may therefore appear that consumption *per capita* was a more important factor than population growth. It was not. Consumption *per capita* increased threefold, *versus* fourfold for population. The twelvefold increase in the total consumption of energy arose as the product, not the sum, of the fourfold increase in population and the threefold increase in consumption *per capita*.

38. The quantitative use of the population/environment equation with all three factors is also best illustrated by example. Suppose one takes as an index of environmental impact the motor-car emissions of lead in the United States since the Second World War. The appropriate measure of "consumption" is vehicle-miles per person, which increased twofold between 1946 and 1967. The impact per unit of consumption in this case is emissions of lead per vehicle-mile, which increased 83 per cent or 1.83 times in this period.<sup>51</sup> Since the population of the United States increased 41 per cent, or 1.41 times between 1946 and 1967, one obtains:

$$\begin{aligned} &\text{relative increase in lead emissions} \\ &= 1.41 \times 2.0 \times 1.83 = 5.16 \text{ or } 416 \text{ per cent.} \end{aligned}$$

Note that the dramatic increase in the total impact arose from rather moderate, but simultaneous, increases in the multiplicative contributing factors. None of the factors was unimportant—if population had not grown in this period, the total increase would have been 3.66 times rather than 5.16 times. (Contrast this result with the erroneous conclusion, arising from the assumption that the contributing factors are additive rather than multiplicative, that a 41 per cent increase in population "explains" only one tenth of a 416 per cent increase in emissions.)

39. Calculations such as the foregoing can be made for a wide variety of pollutants, although it is frequently difficult to uncover the requisite data. Where data are available, the results show that the historical importance of population growth as a multiplicative contributor to widely recognized environmental problems has been substantial.<sup>52</sup>

40. Between 1950 and 1970, for example, world population increased by 46 per cent. By regions, the figures were: Africa, 59 per cent; Asia, 52 per cent; Europe, 18 per cent; Latin America, 75 per cent; North America, 38 per cent; Oceania, 54 per cent; and the

<sup>49</sup> United States of America, Department of Commerce, *Historical Statistics of the United States: Colonial Times to 1956* (Washington, D.C., Government Printing Office, 1960); and United States of America, Department of Commerce, *Statistical Abstract of the United States, 1972* (Washington, D.C., Government Printing Office, 1972).

<sup>51</sup> Barry Commoner, "The environmental cost of economic growth", in *Population Resources and the Environment*, vol. III of Commission research reports of the Commission on Population Growth and the American Future (Washington, D.C., Government Printing Office, 1972), p. 339.

Soviet Union, 35 per cent.<sup>53</sup> On the assumption (which is shown below to be too simplistic) that the patterns of technological change and rising affluence *per capita* that were experienced in this period would have been the same in the absence of these population increases, one can conclude that the absolute magnitudes of damaging inputs to the environment in 1970 were greater by these same percentages than they would have been if population had remained at its 1950 level. Another way of saying this is that, under this simplistic assumption, the magnitude of damaging inputs to the global environment in 1970—a very large figure—would have been only 68 per cent as large if population had not grown between 1950 and 1970. (This follows from the relation: 1970 inputs in absence of population growth equal actual 1970 inputs times 1950 population divided by 1970 population.)

41. Not only has population growth been important in absolute terms as a contributor of environmental damage, but it has been important in relation to other sources of such damage. Perhaps the best way to illustrate this fact is with statistics for energy consumption per person, probably the best aggregate measure of both affluence and technological impact on the environment. One finds that energy consumption per person worldwide increased 57 per cent between 1950 and 1970.<sup>54</sup> By this measure, and under the simple assumption that population growth and trends in affluence and technology were independent, one finds that population growth in the period 1950-1970 was almost equal to the combined effect of rising affluence and technological change as a contributor of damaging inputs to the environment. (The comparison of population growth and energy consumption broken down by major geographical regions is given in table 5.) As is shown below, moreover, the effect of the simplistic assumption of independence of population and other factors is almost certainly to underestimate the role of population, not to over-estimate it.

TABLE 5. INCREASES IN POPULATION AND ENERGY CONSUMPTION *per capita* BETWEEN 1950 AND 1970, BY REGION

(Percentage)		
Region	Population	Energy <i>per capita</i>
World	46	57
Africa	59	73
North America	38	43
Latin America	75	122
Asia	52	197
Europe	18	96
Oceania	54	54

<sup>53</sup> *Statistical Yearbook, 1971* (United Nations publication, Sales No. E/F.72.XVII.1), p. 8.

<sup>54</sup> *Ibid.*, p. 44 and *Statistical Yearbook, 1953* (United Nations publication, Sales No. 53.XVII.9).

42. While it is useful to understand what proportion of the historical increase in specific environmental problems has been directly attributable to the multiplier effect of population growth, there is a more difficult and perhaps more important question than this historical/arithmetical one. Specifically, it may be asked to what extent non-linear effects cause a small increase in population to generate a disproportionately large increase in environmental disruption. These effects fall into two classes. First, population change may cause changes in consumption per person or in impact upon the environment per unit of consumption. Secondly, a small increase in impact upon the environment—generated in part by population change and in part by unrelated changes in the other multiplicative factors—may stimulate a disproportionately large environmental change.

43. An obvious example in the first category is the growth of suburbs in the United States at the expense of central cities, which has resulted in increased use of the motor-car. Another is the heavy environmental costs incurred in the form of large water projects when demand (population times demand per person) exceeds easily exploited local supplies. Yet another example is that of diminishing returns phenomena in agriculture, in which increases in yield needed to feed new mouths can be achieved only by disproportionate increases in inputs, such as fertilizer and pesticides.<sup>55</sup> In each case, the point is that the contributing factors in the population/environment relation can no longer be considered to be independent. In mathematical terms, the equation is non-linear.

44. Many phenomena that have the effect of generating disproportionate, or non-linear, consequences from a given change in demographic variables cannot easily be expressed in the framework of a single equation. One such class of problems involves technological change—the substitution of new materials or processes for old ones that provided the same types of material consumption. Obvious examples are the substitution of nylon and rayon for cotton and wool; of plastics for glass, wood and metals; of aluminium for steel and copper. Such substitutions may be rendered necessary by increasing total demand, or they may be motivated by other factors, such as durability and convenience. Substitutions or other technological changes that are motivated by the pressure of increased total demand, and lead to increases in environmental impact per unit of consumption, should be considered part of the environmental impact of population growth.

45. Environmental disruption is not, however, measured strictly by man's inputs to the environment—what man does to it. Equally important is how the environment responds to what is done to it. This re-

<sup>55</sup> David Pimentel and others, *Corn, Food and the Energy Crisis*, report 73-1 (Ithaca, New York, Cornell University Department of Entomology and Section of Ecology and Systematics, March 1973).

all food can be contaminated naturally by aflatoxins, which have been reported as a carcinogen in certain population groups (liver cell carcinoma).

26. At the psychosocial level, the most important phenomenon is without doubt the change in socio-demographic structures.

27. Overcrowding may affect the behaviour of animals, for example, by a decline in the adequacy of maternal behaviour, and may also affect physiological functions (for example, lethal dosages of drugs vary with the number of animals). In the case of human beings, there is a very clear correlation between, on the one hand, the different urban structures, an excessively high population density and socio-economic conditions; and, on the other hand, the incidence of mental disorders. However, perhaps because of the complexity of these phenomena, no causal relationship has been established.

28. Changes in socio-demographic structures are characterized by, *inter alia*, a change in family structure (from the extended family to the nuclear family) and have a very important effect not only on physical and mental pathology, but on the organization of health services. The disappearance of traditional forms of social behaviour reduces the community's capacity for dealing with its sick or infirm members. Rapid socio-economic development and population expansion have led to an unbalanced age structure. In many parts of the world, there has been an unprecedented increase in the vulnerable groups (children and old people), which has not been accompanied by a proportionate increase in personnel able to provide medical, social and educational services.

CHARACTERISTICS PECULIAR TO THE MORE INDUSTRIALIZED COUNTRIES

29. In economically and technically advanced countries, the factors causing health problems whose magnitude and gravity cannot easily be circumscribed are, at the biological level, the various kinds of physical and chemical pollution of the environment and, at the psychosocial level, the special life-styles and kinds of work resulting from industrialization. Although the effect on health of the major hazardous agents in the environment is relatively well known in the case of occupational exposure or in serious accidents (generally involving exposure for a very limited number of times and for a very limited period to high doses), the individual or combined effect of chronic, low-level exposure to these or other agents on large population groups is, apart from a few exceptions, very little known, if not completely unknown. The same is true of the collective effects of the different kinds of stress in modern life.

30. In the case of air pollution, the three dramatic episodes in the Meuse valley in France (1930), the Donora valley in Pennsylvania, United States of America (1948) and London (1952) provided the main evidence that, in extreme cases, air pollution could be a direct and important cause of morbidity and mortality.

31. Only in the London episode was it possible to demonstrate that an increase in mortality and the presence of smoke and sulphur dioxide coincided with a dense cold fog which lasted for four days. The excess mortality and the increase in morbidity occurred mainly among persons suffering from bronchitis and, to a lesser degree, among those suffering from coronary or myocardial disease. (See table 1.)

TABLE 1. INCREASE IN MORTALITY IN THE LONDON FOG OF DECEMBER 1952<sup>a</sup>

Cause of death	Seasonal norm (deaths per week)	Deaths in week after fog	Excess deaths	Percentage of total excess deaths
Bronchitis	75	704	629	39
Other lung diseases	98	366	268	17
Coronary artery disease, myocardial degeneration	206	525	319	20
Other diseases	508	889	381	24
TOTAL	887	2,484	1,597	100

SOURCE: Royal College of Physicians of London (1970).  
<sup>a</sup> Statistics for the County of London (population 3.3 million).

32. In the case of chronic exposure at a moderate level to atmospheric pollutants, there may be harmful effects on the respiratory tract (bronchitis and emphysema, lung cancer, impairment of functions and sensory irritation of the eyes and nose). Such pollutants may also affect mental health. For example, lead poisoning in children can produce irreparable brain damage with permanent mental retardation. In the slum areas of industrialized cities, children often have symptoms of brain damage due to severe exposure to lead.

Lastly, from the point of view of well-being, living in a gloomy and smoky atmosphere probably has a physiological effect on man which, although less dramatic, may help to disturb his equilibrium and happiness. Few studies have been made on this subject, which will undoubtedly become increasingly important in the future.

33. Among the many chemical substances capable of polluting the air, lead and other toxic metals are the subject of detailed research, as are various inorganic

and organic compounds. However, in general, epidemiological studies are available only in respect of small populations living near the sources of pollution. An expert committee of the World Health Organization (WHO) has defined the criteria for air quality standards in respect of the following pollutants: (a) sulphur oxides and particulate matter; (b) carbon monoxide; (c) photochemical oxidants; (d) nitrogen dioxide.

34. Industrial development has been accompanied by a level of water pollution which makes it increasingly difficult to satisfy growing needs. Water is considered polluted when its chemical, physical and biological properties, or discharges into it of solid, liquid or gaseous substances, are likely to create nuisances or to render the water harmful to public health, welfare and safety, or to domestic, commercial, industrial, agricultural and recreational activities, or to livestock, wild animals, fish and other aquatic life. Water pollution also includes the rise in temperature due to the discharge of hot water (thermal pollution). Health may be affected by the direct ingestion of water (by drinking) or by its indirect ingestion (through food products), by the use of water for personal hygiene, agricultural and industrial purposes, recreational activities or simply by a person's living close to polluted water. Although, in the most highly industrialized developed countries, the risk of accidental biological contamination of water cannot be discounted, attention is devoted in particular to the risks resulting from chemical and radio-active pollution, especially as a result of outbreaks of mercury or cadmium poisoning.

35. In *International Standards for Drinking-Water*, minimum standards currently attainable in all countries of the world are proposed, with reference to five classes of quality parameters: biological, radio-active, toxic and chemical, and characteristics of acceptability. (See table 2.)

36. Food may also be biologically, chemically or radio-actively contaminated, a further risk thus being added to the other health hazards. This also applies in the case of soil pollution, which, in industrialized countries, is due mainly to:

- (a) the use in agriculture of a very wide variety of chemicals;
- (b) the dumping of large masses of waste materials from the mining of minerals and the smelting of metals;
- (c) the dumping of domestic refuse and solids resulting from the treatment of domestic refuse and industrial wastes.

37. One of the most widespread annoyances of industrial civilization is that caused by noise. Whether in connexion with the work environment, with highway, urban or air traffic or in the home, the sources of noise are numerous, the noise level is high and the effects on health and well-being are manifold.

38. Repeated exposure in the course of employment to high noise levels may lead to deafness. To a lesser degree, the impairment of hearing acuity with age may be accelerated by exposure to noise. In addition, noise

has a number of non-specific physiological effects which are not constant and whose impact on health is not clear, such as changes in the cardio-vascular and respiratory systems, in the eyes, in galvanic skin responses and in the blood and other body fluids.

39. The psychophysiological effects are felt mainly in connexion with sleep, the disturbance of which may, in the long run, adversely affect health, but, in this regard, epidemiological proof is lacking. The annoyance caused by noise, and the ensuing discomfort, also have an increasing psychosocial effect, both individually and collectively, on work performance.

#### *The consequences of industrialization*

40. Although working conditions have progressed considerably since the industrial revolution of the nineteenth century, industrial development, productivity, changes in technologies and in production methods still give the work environment a special dimension which is important to physical and mental health, particularly since it is indissolubly linked to general living conditions and to the environment generally.

41. Occupational diseases and injuries result from specific exposure at work but, in addition, work exposure may aggravate certain cardio-vascular, respiratory, nervous or mental diseases, for example, or may

contribute to the outbreak of diseases of multiple aetiology.

42. All the environmental pollutants, whether physical, chemical or biological, may be present in the work environment and generally in much higher concentrations than in the environment as a whole. Furthermore, the work environment has hazards of its own. For a large number of substances, an exposure level has been defined below which the worker's health is unlikely to be endangered (in terms of the threshold limit value, the maximum allowable concentration or the permissible dose).

43. The advances in work hygiene and safety have had the effect of reducing the risk of occupational exposure in large-scale modern industries. As a result, attention has been turned to health and welfare problems connected with psychosocial factors, with working and living conditions and with urban, transport and leisure problems—all of which interact in a complex manner.

44. A high degree of job mechanization may increase psychosomatic disorders, reduce job satisfaction and contribute to a higher rate of absenteeism. Factors such as interpersonal relations at work, work stability, shift work, speed and safety are important. Workers engaged in repetitive tasks, controlled by machines, derive less satisfaction from their work.

45. Shift work creates a psychosocial working environment that may adversely influence the health of the worker. Night work, and the change of working hours from one shift to another, may subject the workers to certain stresses. Such stresses affect the nervous system, increasing the frequency of peptic ulcer and of nervous symptoms, such as fatigue, nervousness, irritation and insomnia. These nervous symptoms are usually related to lack of sleep, which in turn may be related to housing conditions and especially to disturbance of sleep by noise during the day if the worker is on night shift.

46. Gastro-intestinal diseases are of multiple aetiology and the work environment may be a contributing factor, especially where there is emotional or psychological stress at work. Shift workers, for instance, may have a higher incidence of peptic ulcer than day workers.

47. It has often been said that the ever-increasing pace and stress of life, together with industrialization, brought about an increase in the incidence of mental disorders. That is probably true for psychosomatic and psychoneurotic illnesses, but there is no conclusive evidence on this subject.

48. On the other hand, epidemiological studies have shown that the incidence of functional psychoses, such as schizophrenia, was not affected by the level or speed of social and economic development. The constant increase in the number of people needing medical, psychiatric or social care is due to: (1) changes in social structures, the increase in the number of specialized jobs making it difficult to integrate the hand-

icapped and the mentally retarded; (2) change in the structure of the family, nuclear families being generally less capable than extended families of solving the problems of the handicapped; and (3) increase in mental health services, enabling a more accurate assessment to be made of the incidence of mental illness.

49. In order to meet the demand for unskilled labour, many countries use migrant workers. In Europe, there are 11 million migrant workers, coming from the economically less developed countries of Europe and Africa. These uprooted, transplanted, poorly integrated workers live in conditions which represent in most cases a potential danger to their health and welfare. Health services for migrants are often inadequate and do not make it possible for health problems to be identified and treated rapidly. The migrant rarely finds in a foreign country the social structures to which he was accustomed in his own country, so that even trivial problems can have disastrous consequences for mental health.

50. There are three typical case histories for migrant workers:

(a) they may bring a disease with them when they come from a region in which communicable diseases are endemic;

(b) they may acquire a disease in the host country, the most prevalent being tuberculosis, the incidence of which is estimated to be from four to five times greater among migrant than among native workers;

(c) they may have adaptation difficulties arising essentially from problems of language and culture, "culture shock", the displacement syndrome and "foreigners' fever" being excellent examples of this kind of illness which are especially likely to occur when the migration was involuntary.

#### *Importance of mental, chronic and geriatric diseases*

51. Despite the risks, it must be admitted that if the life expectancy of a population is taken as an indicator of health, industrial development and urbanization have been accompanied by a spectacular increase in life expectancy and that the general state of health is better in urban than in rural areas. However, in the most highly industrialized countries, the increased life-span and the drastic changes in way of life and in the environment are associated with a greater incidence of non-communicable chronic and geriatric diseases. The variety of mental and psychosomatic illnesses is more obvious and calls for closer study and increased action.

52. It is to be hoped that scientific progress will help to reduce morbidity and prolong life. However, efforts to improve health should in future take the following direction: on the one hand, greater care will have to be taken to protect the essential biological ecosystems and prevent any further deterioration in the environment; on the other, closer attention will be given to psychosocial factors, not only to prolong human life and combat disease, but also to make life happier and more harmonious.

# POPULATION GROWTH AND CLIMATE MODIFICATION

## United Nations Environment Programme

### CLIMATIC FLUCTUATIONS AND THEIR CAUSES

1. In recent years, the problem of climatic fluctuations and of their physical causes has increasingly attracted the attention of scientists. Meteorological observations have revealed the occurrence of regional fluctuations. Distinct increases of temperature and/or rainfall do exist in some areas in marked contrast to similarly distinct decreases in other areas. Hemispheric or global averages are little affected. Only small temperature changes are observed (fig. I), while the figures of the global water balance between precipitation and evaporation are hardly sufficiently precise—due to the lack of data above vast ocean areas—to allow an evaluation of small deviations.

Figure I. Temperature fluctuations since 1880, averaged for the northern (N) and southern (S) hemispheres

Note: N\* = corrected by omitting urban stations.

2. Climate can only be understood as a common property of the geophysical system: atmosphere, ocean and ice as a complex of fields which encompass many built-in feedbacks and instabilities. The fields of temperature, density, pressure and wind, of water-vapour with its essential phase changes, vary with time. The system is driven by energy exchange processes at the earth's surface and within the atmosphere at different scales, all with a quite diffuse pattern of sources and sinks. The most powerful energy conversions are connected with the hydrological cycle of evaporation, precipitation and run-off. To understand the mechanism of climatic change and of climate modification, one must simulate the atmospheric-ocean-ice system in a physico-mathematical model. If designed as the real earth with its land-sea distribution, its mountains and its continental and marine ice-cover, such models are of

the highest complexity. From the scientific point of view, climatic models are of the utmost importance, even if they have reached only an early stage of development. However, for the purpose of the decision-makers, they do not currently permit more than some general conclusions.

3. Climatic fluctuations were observed long before meteorological instruments were developed: even during the past 1,000 years the extension of the Arctic sea ice has greatly changed, with a rather dramatic effect on human settlements and economic conditions in Iceland and Greenland. Similarly, the vegetation cover in marginal parts of the Sahara and in the arid areas of the Near and Middle East has been drastically reduced since the beginning of historic times. Only after many careful investigations has it become obvious that this disastrous change is not primarily caused by climatic variation, but by the increasing human impact on the fragile ecosystem—the hunting and extinction of predators and the destruction of vegetation by a growing number of domestic animals. After the rapid development of industries, man's inadvertent impact on climate has now become a matter of great concern among scientists.

4. Climate is controlled by the solar radiation, on the one hand, and by the properties of the geophysical system (atmosphere + ocean + ice (including the surface of the continents)), on the other. Table 1 gives a review on the most important factors controlling the very nearly balanced state of the system. The energy input by the sun's radiation has been considered by the majority of astronomers to be constant with time, at least in the "human" time-scale in the order of 100 years. There is, however, some evidence of small

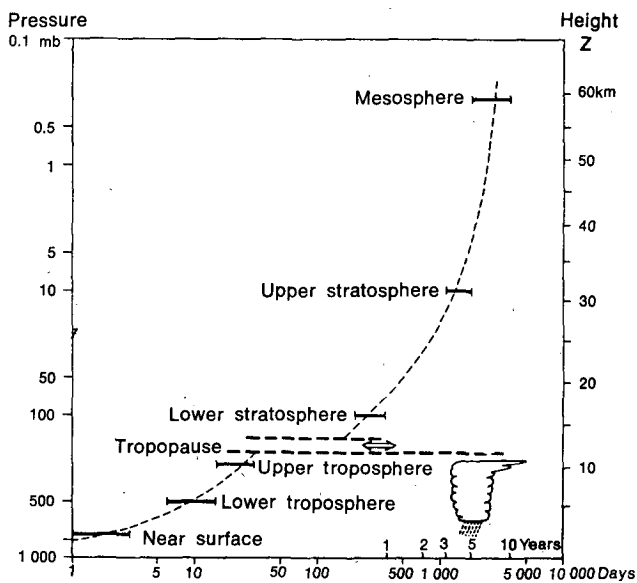

TABLE 1. CAUSES OF LARGE-SCALE CLIMATIC FLUCTUATIONS

Natural causes	Man-made causes
<i>Astrophysical:</i>	
Changes of the solar energy flux ("solar constant")	CO <sub>2</sub> increase Particulate air pollution Surface albedo changes Energy production and consumption
<i>Geophysical:</i>	
Stratospheric dust after volcanic eruptions Antarctic ice surges	<i>Internal parameters (feedback):</i> Changes of hydrological cycle (reservoirs, irrigation, deforestation) Cloudiness changes
<i>Internal parameters (feedback):</i>	
Changes of sea ice cover	

fluctuations of the so-called "solar constant", but as these observations have been taken within the stratosphere, they can also be interpreted as results of stratospheric turbidity due to volcanic eruptions. Such eruptions inject large amounts of small particles and particle-producing gases into the stratosphere (above 16 km in the tropics; above 8-11 km in middle and high latitudes). Due to the lack of clouds and precipitation processes in this layer, these particles remain, on average, a few years in the stratosphere (fig. II), in contrast to a residence time of a few days or weeks in the troposphere. Stratospheric particles spread in a few months above the whole globe and concentrate later in the polar regions. They absorb and scatter a small part of sun's radiation and therefore reduce slightly (up to 1-2°C) the temperature near the earth's surface in the first years after a large volcanic eruption (as in 1963 at Agung in Bali, Indonesia).

Figure II. Residence time of aerosol particles in the atmosphere

5. Recent studies have indicated the probability that the large variations in the amount of subantarctic icebergs are due to surges of the 2000-m thick Antarctic ice-cap, which is partly based on a melting layer. Since these surges are quite rare events, very little is known about their geophysical conditions. Their climatic effect consists of an immediate cooling of the subantarctic oceans (by melting) and in an increase of the albedo (reflectivity) of the surface, both effects probably lasting during several decades (or even centuries).

6. The above-mentioned fluctuations of the shallow Arctic sea-ice—with an average thickness of only 2-3 metres—are best documented in the time during which the coasts of Iceland were blocked by ice (fig. III). There exists a marked correlation between these fluctuations and the temperatures of the surface of the sea and air. It is very difficult to distinguish here between cause and effect, because of the (non-linear) interaction and

Figure III. Duration of blocking of the coasts of Iceland by Arctic sea-ice

the feedback mechanism involved (see also paras. 30-35). At any rate, the area covered by ice has varied by at least 2 million km<sup>2</sup> (about 20 per cent) during the past 1,000 years, and the thickness has also most probably varied by about 20 per cent.

7. A numerical comparison between natural and man-made climatogenetic factors can currently be based only on reasonable estimates of their energetics (table 2). From one-dimensional radiation models it can be demonstrated that the most prominent natural geophysical factors generally lead to a cooling—of from one to three years duration in the case of large volcanic eruptions, and of 20-100 years in the case of medium-scale Antarctic ice-surges (as in the nineteenth century). Small variations of the solar constant are still controversial; however, variations of more than 1.0 or 1.5 per cent can be safely excluded.

8. Since the greatest part (about 82 per cent) of the radiation budget of the earth's surface is used to evaporate water, only the latitudinal and regional differences of the heat budget are responsible for the atmospheric circulation which controls climate. These climatogenetic processes need, primarily, not more than a few thousand terawatts (TW). They are intensified by the redistribution of energy, especially of latent heat of condensation. Comparatively small changes of cloudiness—which are, at present, undetectable—or evaporation contribute a few hundred terawatts. Changes of polar ice-cover (as observed during the past two centuries) subtract or add an energy amount in the order of 100-200 TW. This is the order of magnitude of recent climatic fluctuations as caused by natural effects.

#### INSTABILITY OF CLIMATE

9. Within the atmosphere, several instabilities are well known which are responsible for the vagaries of weather, such as local showers and thunderstorms, as well as the formation and decay of cyclones and anticyclones. Only recently has the existence of instabilities of the climate been revealed in a much larger time-scale of years and decades. Among these are regional instabilities, especially in the rainfall régime of tropical areas. One of the best examples is the upwelling of cool water along the equator in the Pacific and Atlantic, where water temperatures are positively correlated with extremely large rainfall anomalies, occurring simultaneously over distances up to 12,000 km in the Pacific, caused by a sort of flip-flop mechanism in an

TABLE 2. ENERGY ESTIMATES OF LARGE-SCALE CLIMATIC FLUCTUATIONS

(Unit:  $10^{12}$  watts = 1 terawatt (TW))

<i>(a) External parameters</i>		
Solar constant (extraterrestrial)		173,000 TW
Radiation budget (earth + atmosphere system)		123,000 TW
Radiation budget, earth's surface		48,700 TW
Geothermal heat flux		32 TW
Depletion of radiation due to stratospheric dust		-2000 TW (maximum)
Antarctic ice-surges		-50 to 100 TW per $10^6$ km <sup>2</sup>
<i>(b) Internal parameters (with feedback)</i>		
Change of cloudiness ( $\pm 1$ per cent)		$\pm 350$ TW
Change of evaporation: equatorial oceans		$\pm 300$ TW
Area change of Arctic sea-ice		$\pm 50$ TW per $10^6$ km <sup>2</sup>
Energy budget of photosynthetic processes		$\pm 92$ TW
<i>(c) Man-made parameters</i>		
	1970	2000 (projected)
Increase of CO <sub>2</sub> content	+ 1.5 TW	+ 2.4 TW
Energy production	+ 8 TW	+ 40 TW
Tropospheric turbidity N. Hemisphere	+ 40 TW (total)	
Tropospheric turbidity: industry and cities	+ 2 TW	
Tropospheric turbidity: bush-fires, vegetation destruction	+ 5 TW	
Heat of savannah bush-fires	+ 3 TW	
Water consumption of irrigation to air	+140 TW	+390 TW
Conversion of tropical rain-forest	- 17 TW per $10^6$ km <sup>2</sup>	

irregular time-scale of 1-7 years with very short transition periods. Another example is the sudden drop of the Nile floods (as caused by the summer rainfall in the Ethiopian highlands) by 20 per cent in 1898; similar changes have been found in all African lakes between latitudes  $15^{\circ}\text{N}$  and  $15^{\circ}\text{S}$ . Recent investigations appear to indicate that many regional anomalies—e.g., droughts in central India, in the Sahel belt of Africa and north-eastern Brazil; the disappearance of cold nutrient-rich upwelling water along the coasts of Peru and Ecuador, known as El Niño, together with the above-mentioned equatorial upwelling in the Pacific—occur more or less simultaneously and affect increasingly the fragile economic balance of many less developed tropical countries.

10. The most recent example of a coincidence of these anomalies was 1972, partially extended to 1973. The coincidence of these anomalies—which have been observed, with irregular intervals, during the past 80 years—leads to a nearly simultaneous occurrence of severe food shortages (here including the protein production of the world's largest fishery industry in Peru). With increasing population, the sensitivity of national economics to such anomalies rises sharply; this is especially true when similar droughts and drops of the food production occur in higher latitudes, e.g., in Canada, the Union of Soviet Socialist Republics and the United States of America. The geophysical conditions of such coincidences—which are certainly not random—are not yet completely understood.

11. Even more interesting from the point of view of the climatologist, but much less frequent, are global-

scale instabilities at both polar regions, the shallow Arctic sea-ice and the immense continental ice-cap of the Antarctic. It is impossible to review here in detail the possible occurrence of large-scale Antarctic ice-surges, which could have produced, in a few decades, a global cooling of the same magnitude as the last glaciation as well as a sharp eustatic rise of the world's sea-level by 15-20 m.

12. Such events are certainly rare, occurring only in a time distance of about 10,000 years. Investigations of the geophysical conditions of these surges will now be begun. However, there is sufficient evidence of a minor event of this kind around the middle of the nineteenth century, probably correlated with a cool (and probably rainy) period in tropical and northern latitudes.

13. Another instability of this kind—apparently somewhat slower and less acute—can be observed in the Arctic, in correlation with the varying extension and thickness of the sea-ice (see paras. 30-35).

14. The physical causes of these global instabilities are found in an equilibrium between the surface albedo (which depends very strongly upon the area extension of snow and ice) and the temperatures near the surface. The available evidence shows that this relation controls largely the time variations of hemispheric (or global) temperature averages, and furthermore (at least partially) the average position of the large-scale climatic belts. This equilibrium is quite sensitive against man-made modifications of one or another climate-producing effect (see paras. 15-22).

## MAN-MADE EFFECTS ON CLIMATE

15. The impact of man's activity upon climate began in quite early times and under quite primitive conditions. It was his ability both to light a fire and to destroy the natural vegetation. From the physical point of view, several impacts have to be distinguished.

16. First is the increase of carbon dioxide. According to a number of measurements at the beginning of industrialization in the developed countries (between 1870 and 1900), the CO<sub>2</sub> content of the air was about 290 parts per million (part per million = 10<sup>-6</sup> of volume). Owing to the burning of fossile fuels—coal, lignite, oil, natural gas—the CO<sub>2</sub> content of the air has increased to about 324 ppm now. The rate of increase varies around 0.7 ppm per year. Since only half of the CO<sub>2</sub> production is stored in the air, the other half in the ocean or in the biosphere (vegetation), it will further increase. Extrapolation for the year 2000 leads to a CO<sub>2</sub> content of 370-380 ppm, and to a value of more than 400 ppm in the first decades of the next century. Absorption of infra-red radiation by carbon dioxide leads to rising temperatures, especially in the stratosphere. Near the surface, the warming effect is relatively small—about 0.4°C for an increase of 50 ppm—but not negligible compared with the observed changes.

17. The air pollution, consisting of small dust particles (with a diameter between about 0.1 and 10 microns: 1 micron is 0.0001 mm) has a natural background, caused by volcanic gases, ocean spray and forest-produced hydrocarbons. Man-made particles are partially produced by such local sources as cities and industries. More essential (and frequently underrated) are the non-industrial air-pollution sources: the dust-raising role of the destruction of the sparse vegetation in the marginal parts of arid areas, e.g., by over-grazing ("man-made desert"), and the man-ignited bush-fires in the semi-humid tropics; both occur over areas of 10 million km<sup>2</sup> each, in contrast to the extension of industrial pollution over an area of only 500,000 km<sup>2</sup> altogether. Measurements of the atmospheric turbidity during the dry season in this area reveal values higher than those over the centres of industrialized cities, e.g., Tokyo. The effect on climate is twofold: a reduction of the sun's radiation in the visible part of spectrum as well as absorption and emission of infra-red radiation. The latter effect causes warming (especially in night-time) and is usually stronger than the first one. In areas of strong pollution—marked by a drastic reduction of visibility and by a whitish colour of the cloudless sky—it may reach 1-2°C or even more. (To avoid misinterpretation, it should be mentioned here that stratospheric dust also absorbs and emits radiation—but at very high altitudes and thus it is ineffective near the surface.) Under humid conditions, the average residence time of particles in the troposphere is only a few days (fig. II); under arid conditions or in the dry season, it can rise to several decades. Air pollution has increased not only in industrial areas, but—by a factor of 2-3—above the

North Atlantic as revealed from atmospheric electricity data, while the southern hemisphere has remained rather unpolluted. The observed decrease of air pollution in some industrial areas is only local; in many relatively "clean" rural areas it still increases steadily.

18. Small changes of the surface albedo are frequently connected with agricultural operation and land-use practices. Here it is very difficult to give representative figures. It can be stated that with brighter colour of the vegetation and/or the soil (as seen from the air) the albedo increases and the net radiation available at the surface decreases, which would also reduce the evaporation.

19. In the long run, the effect of energy consumption will become the greatest possible risk to climate. According to the basic laws of physics, all energy is finally converted into heat and adds therefore to the natural energy budget of the atmosphere-ocean system. This is mainly so for energy from fossil and nuclear sources—in the case of solar, hydroelectric and geothermal heat only a redistribution of energy takes place. Currently, the total energy consumption by man has surpassed 8 terawatts (10<sup>12</sup> watts, see table 2). This is only a minute contribution to the total heat budget of the earth's surface, but—considered above the continents alone—about the same as the geothermal heat flux from the earth's interior (9 TW) and somewhat smaller than the sum of the photosynthetic life processes in the whole biosphere. If the storage of fossile energy in the form of coal, oil etc. has remained constant during the past 500 million years, the reserves stored during about 500,000 years or more are now burned every year. It is therefore vital to look for other energy sources to be used in the future.

20. The small contribution of man's activity to the atmospheric energy budget is misleading since it does not take into account the local energy distribution and its foreseeable development. Man's energy consumption increases exponentially by 5-6 per cent per annum and in some countries (e.g., Japan) by more than 10 per cent. An annual growth rate of 5.5 per cent is equivalent to a rise by a factor of 5 every 30 years, i.e., within one generation. Assuming the economic growth rate to be constant, the current contribution of 8 TW is expected to increase, after about 60 years, to 200 TW, as a permanent addition of energy to the geophysical system. Today it is mostly concentrated in temperate latitudes of the northern hemisphere, to about two thirds on either side of the Atlantic. This may change in the near future, when more and more developing countries enter into the industrial era. On this assumption, man's energy consumption will reach, a few decades after the beginning of the next century, the level of the observed natural climatic fluctuations—but then with a persisting one-directional effect: of warming. This could have a dramatic effect in one of the most sensitive areas of the geophysical system—in the Arctic (see paras, 30-35).

21. On a local scale, this combined effect of air pollution, CO<sub>2</sub> and additional energy input is well known

from urban climates. The "urban heat island" is always warmer than the surrounding area, mostly during the night and in the winter season. Local heating produces weak local wind systems converging at the heat centre. Under unstable weather conditions, this also causes an increased frequency of heavy showers and thunderstorms, displaced somewhat downwards with the prevailing wind direction. This local effect can be beneficial—earlier appearance of spring flowers, shorter duration of snow cover and other secondary effects are observed.

22. At a regional scale, the impact of man's energy contribution is beginning to be no longer negligible (table 3). If this energy is distributed evenly throughout

an area, in a densely populated industrial area (e.g., the north-western part of the Federal Republic of Germany) a typical energy contribution of about 10 watts/m<sup>2</sup> over an area of 10<sup>4</sup> km<sup>2</sup> is obtained as compared with a natural radiation budget of about 60 watts/m<sup>2</sup>. Outside of industrial areas, such an even distribution is certainly unrealistic. The figures for several developed countries show that man's impact on the climate-producing energy budget now approaches about 1 per cent of the natural budget (which is, in the global average, nearly 100 watts/m<sup>2</sup>). Since the energy consumption *per capita* is strongly correlated with the gross national product, one has to expect drastic future changes in this distribution.

TABLE 3. ENERGY CONSUMPTION, 1968

MAN'S IMPACT ON THE WATER BUDGET; THE ROLE OF  
VEGETATION AND LAND-USE

23. More urgent than the man-made input of energy into the geophysical system is the increase in the consumption of fresh water. From the standpoint of climate, one has only to consider that part which is evaporated and does not return to the rivers (table 4),

which currently contributes about 3 per cent of the annual evaporation of the continents and consumes more than 5 per cent of run-off. The average fresh-water consumption increases by 3-4 per cent per annum. This growth rate is certainly greater than the growth rate of the population. It must be at least maintained, because of the increasing need of the new "miracle" crops and the urgency to nourish a rapidly growing population.

TABLE 4. WATER CONSUMPTION  
(Cubic kilometres per annum)

TOTAL	2,848	1,051	1,797	12,700	7,790	4,910

SOURCE: M. J. LVovich, *Vodnie ressuissi budushevo* (Water Resources for the Future) (Moscow, 1960).

Note: For comparison: natural run-off (continents) 35,000 km<sup>3</sup>/a;  
natural evaporation (continents) 65,000 km<sup>3</sup>/a.

24. Assuming the area of potentially arable soils in semi-arid and arid countries to be 7 million km<sup>2</sup> (including 2.4 million km<sup>2</sup> in extratropical latitudes), effective irrigation (with 2 m per annum in tropical and subtropical areas, but only 1 m per annum outside the tropics) needs a total of 11,600 km<sup>3</sup>, i.e., about one third of the total continental run-off, and nearly three times the estimate given by Lvovich for the year 2000. Since the rivers feeding the arid belt yield only a small fraction (about 800 km<sup>3</sup>/a), desalination of ocean water will be necessary, a process which demands much energy. While desalination of ocean water by distillation needs 47-60 kWh/m<sup>3</sup> (as in the area of Hong Kong or in Kuwait), the process of reverted osmosis needs only 3 kWh/m<sup>3</sup>, but has not yet been developed to technological maturity. Even if this technique can be used in the foreseeable future in large plants, desalination of 6000 km<sup>3</sup>/a (or one half of the above-mentioned total) would need about 2 terawatts, i.e. one fourth of the current world energy consumption. Higher estimates of the potentially arable area would even more aggravate the situation.

25. The conversion of the natural vegetation by man has, to a varying degree, changed the climate-producing factors of the surface over at least half of the continental area, i.e., over about 15 per cent of the total surface of the earth. Without going into the details of a physical theory of climate, only the following factors are mentioned here: (a) surface albedo (see paras. 15-22); (b) evaporation (of soils) and transpiration (of plants), humidity of air; (c) soil moisture and heat conductivity; (d) surface roughness and wind speed.

26. Among the most efficient conversions of natural vegetation are the irrigation of arid areas—the total irrigated area is now about 2 million km<sup>2</sup>—and the clearing of forests and their use as grasslands. While in the first case the evapo-transpiration increases sharply from zero to values near 2 m per annum, deforestation—which was begun by early man several thousand years ago—tends to decrease the original evapo-transpiration by values up to 20 per cent and more. Both types of conversions have very little effect on rainfall: 87 per cent of the water vapour in the atmosphere comes from the ocean. An evaporating water droplet remains, on average, 9 days in the atmosphere before it rains out once more. During this time it usually travels several thousand kilometres from its origin. But these conversions have a marked effect on local (and regional) evaporation and on run-off, as well as on the ground-water reserves. In several arid countries (for example, at the northern margins of the Sahara), the deep ground-water reserves are fossil. They were formed under the climatic conditions of the last ice-age 20,000 years ago and are not renewable when over-exploited. In arid areas also, no relief is to be expected from artificial rainfall techniques. These are only effective under very special climatic conditions with high humidity and a great amount of low clouds.

27. Of great importance is the more or less complete degradation of the natural vegetation, caused by increasing population and their immediate needs for food, milk and firewood. The limits of the Sahara desert are said to expand annually by about 1 km on both sides. This statistical average means an area increase of 10<sup>4</sup> km<sup>2</sup> per annum. This man-made (or goat-made) effect is in fact terrifying. It has certainly contributed to the current situation (1972-1973) in the West African Sahel belt, which is worse than during a similar drought lasting seven years between 1907 and 1914. In many other areas, the search for firewood has destroyed even large full-grown forests, for example, in the Mediterranean and in many mountains of the Near and Middle East as far east as Afghanistan and Kashmir. In tropical rain-forests, the soil is so leached that after its clearing the vegetation degrades mostly to useless grasslands (e.g., in the central hills of Fiji).

28. In most of these cases, the climate itself is but little modified; but the degradation of soils and vegetation, the lowering of the ground water and the tendency to soil erosion and disastrous floods interrupted by long dry periods lead to a serious deterioration of the physical and biological environment. This damage is in some cases reversible before the soil is destroyed—but only when protecting the area completely against any kind of use. In the remaining parts of the equatorial rain-forest, e.g., in the Amazon and Congo basins, even a reduction of rainfall after large-scale deforestation (as a consequence of a reduction of area-averaged evaporation) is possible.

29. In already over-populated areas of the tropical and subtropical belts these modifications have already reached a dangerous limit. They affect certainly not less than 20-30 million km<sup>2</sup> and spread rapidly with the increase of population, of food production and of over-grazing. Their effect on the local and regional water budget is difficult to assess numerically, due to the lack of data from an intact natural state.

#### THE PROBLEM OF THE ARCTIC SEA-ICE

30. Here one is confronted with a serious question: the extent to which the exponentially increasing consumption of fresh water and energy can modify the world's climate—especially when taking into account its potential instability. An increasing number of far-sighted scientists—looking beyond the relatively stable period of the past 200 (or even 1,000) years—envisages the potential risk of large-scale climatic modifications. Due to the quite different regional situation and to other restrictions, it is hardly possible to set a limit with a marker, "Trespassing Prohibited". Assuming 200-300 TW as the best available estimate of natural climatic fluctuations, one can try to extrapolate the current trend of man-made effects. Raising the consumption of (fossil and nuclear) energy by a factor of 20-30 will reach this critical level. Raising the fresh-water consumption by a factor of 4-6 will certainly exhaust many regional

reserves. Desalination of the oceans in a large manner will certainly aggravate the energy situation. If an extrapolation of the current exponential growth rates is allowed—this is well beyond the limitations of this report—one must conclude that a critical threshold can be reached within 50-60 years. Taking into account the potential instability of the climate and the different intensity of man's impact, the threshold could be reached even earlier. Several recent experiments to simulate climate with physico-mathematical computer models have revealed an astonishingly high degree of sensitivity of the geophysical system. These results—regardless of the inherent deficiencies of some models—should be taken with caution, but yet rather seriously.

31. The greatest risk of a large-scale climatic instability at this time is that of a drastic modification of the Arctic sea-ice, which is apparently in a delicate state of balance. This is especially true because of the general trend of warming by all essential man-made modifications, concentrated (at least now) in the Atlantic section of the mid-latitudes.

32. Historical and geological evidence shows that some marginal parts of the Arctic (around Greenland and the Canadian Archipelago, and along the Siberian coast) had been ice-free during the post-glacial optimum 5,000 years ago, but that the central part has remained unaltered for about 120,000 years. What are the inadvertent consequences of man-made environmental changes on this delicately balanced state? The problem has been carefully investigated and simulated in an one-dimensional model of the air-sea-ice system, showing that in each melting season (from mid-June to end of August) about 50 cm of surface ice is melted, while during the rest of the year the same amount freezes from below depending upon many oceanic and atmospheric quantities. Figure IV gives an idealized cross-section of the stratification of the Arctic Ocean. During the next few decades one has to expect three significant actions of man, unintentionally affecting this sensitive balance in the same direction:

(a) The need for additional fresh water in arid Central Asia (USSR) will be met by the diversion of the large Siberian rivers, Ob and Yenissei; a similar development can be expected in the Mackenzie catchment in Canada. With such a reduction of fresh-water inflow,

the salinity of the top layer of the Arctic Ocean will increase and in turn ice growth will decrease. When the density—here depending mainly upon salinity—of the top layer reaches that of the underlying water, strong vertical mixing will prohibit ice production. With a conservative estimate of the loss of fresh-water inflow (12 per cent) this event can be expected after some 50-100 years, neglecting, as a first guess, positive or negative feedback effects involved;

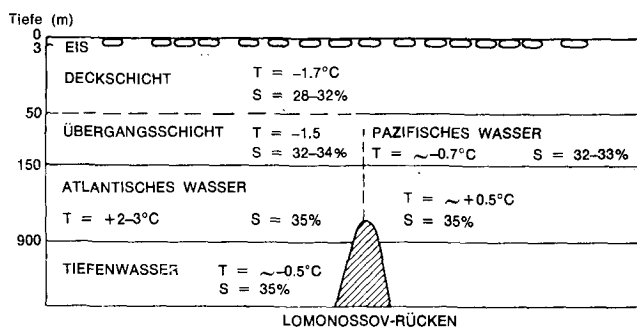

(b) Even more essential is the man-made warming of air and water, concentrated in the Atlantic section. Assuming the actual flux of air across latitude 70°N to remain constant, but with a warming of 1°C, this would be sufficient to reduce the mass-budget of the sea-ice by 4 cm per annum. This effect alone may also cause a disappearance of the ice in less than a century. Man-made warming of the ocean should be smaller, but not negligible, and adds to this result;

(c) As a consequence of the current energy crisis, the oil reserves of the Alaskan Shelf will be exploited in the coming decades. In this case, leaking oil can hardly be prevented from spoiling the snow surface of the ice floes—where the bacteriological processes act extremely slowly, due to the low temperatures—and lower their albedo, which in turn leads to a significant lengthening of the summer melting period.

33. All these effects are working together. Their combination can be expected to lead to a total destruction of the ice-cover in a period of a few decades. Once completely destroyed, the sea-ice cannot be rebuilt under current climatic conditions, except during winter in the coastal belt. This process is almost certainly irreversible. In this case the change of the heat budget will be quite dramatic. Instead of 35 per cent storage of the incoming radiation during the 24-hour polar summer, about 90 per cent would be absorbed and stored in the ocean. While the winter temperatures should increase from about -32°C to near 0°C, the summer temperatures rise only from about 0° to 3-5°C.

34. Such a change must be accompanied by marked changes of the global climatic pattern. It is impossible to discuss here the results of the investigations of this situation, as undertaken from several groups in the USSR, in the United States of America, in the United Kingdom of Great Britain and Northern Ireland and in the Federal Republic of Germany, based on different models. While the summer conditions are only little affected, the modification in winter should be quite dramatic. In contrast to general belief, it could lead to marked cooling above mid-latitude continents and to a northward displacement of the subtropical anticyclonic centres with a marked change in the path of cyclones. This displacement of the subtropical high-pressure belt must strongly reduce rainfall in such sensitive areas as the Mediterranean, the Near and Middle East and California (United States of America). One should also expect significant changes in the tropical rainfall distribution, even beyond the equator. Certainly many further investigations with more realistic mathe-

Figure IV. Vertical stratification of the Arctic Ocean

matical models are necessary, before the climatic consequences of an ice-free Arctic Ocean can be outlined with sufficient accuracy.

35. If unlimited growth of population must be correlated with unlimited economic growth, including energy consumption, very serious risks of irreversible global-scale climatic modifications must be envisaged. This is especially true for the fresh-water budget (and thus for food production); here an exhaustion of available reserves is to be expected in several areas. Desalination of sea water is possible at high costs, but will aggravate the energy situation. Such climatic changes may perhaps be beneficial in some regions. However, their effect—especially in respect to the fresh-

water balance—certainly will be disastrous to many other densely populated areas. Obviously, this risk will provide one of the earliest absolute limitations to population growth.

#### ANNEX

##### Glossary of terms

Albedo: reflectivity of the surface (reflected radiation as a percentage of the incoming radiation).

Anticyclonic centre: centre of high air pressure.

Eustacy: world-wide change of sea level as contrasted with local diastrophic uplift or subsidence of land.

Evaporation: loss of water vapour from soil or from water surfaces.

Evapo-transpiration: loss of water vapour from soil and plant cover.

Irreversible: never to be reverted.

Precipitation: sum of rainfall, snow and hail.

Solar constant: radiation of the sun at the upper limit of the earth's atmosphere on a surface perpendicular to the rays.

Stratosphere: atmosphere between 16 km (in the tropics), 10-12 km (in higher latitudes) and 50-km altitude.

Terawatt:  $10^{12}$  (or 1,000,000,000,000) watt — unit of energy.

*Biological terms*

Ecosystem: ecological system of plants and animals living together in a uniform environment.

Osmosis: penetration of a liquid through a membrane.

Photosynthesis: production of living matter by converting the sunlight.

## NATIONAL POLICIES AND EXPERIENCES RELEVANT TO URBAN DEVELOPMENT: AN EVALUATION\*

Lloyd Rodwin\*\*

1. This paper deals with the lessons that interested decision-makers—especially those serving developing countries—might draw from the experiences of those countries which have attempted to devise policies to guide urban development. The inferences are based on the programmes of many different countries in all the major regions of the world. However, particular emphasis is placed on the experiences of five countries: France, the United Kingdom of Great Britain and Northern Ireland, the United States of America, Turkey and Venezuela.<sup>1</sup> The first three are relatively advanced economically; the others are not. The evaluation considers the way in which such policies evolved in developed and developing countries, the goals sought, the methods employed, how and why programmes differed and resembled each other, how successful the efforts have been and some of the lessons which can be drawn from these experiences. It concludes with seven cautionary observations—inferred from an evaluation of these experiences.

### GERMINATING CONDITIONS

2. Two conditions generate urban growth strategies: growth problems must be recognized as critical; they must also appear capable of solution. Otherwise, it would be difficult to persuade the central Government to redefine its aims and to reorganize its tools and organizations. Governments, like people, shy away from abstract issues and certainly do not bestir themselves very much unless an issue threatens to be persistent, prominent and likely to cause trouble if ignored. Once an issue acquires these characteristics, however, it becomes part of the agenda of government and takes the status of what Hirschman has called a "privileged" problem.<sup>2</sup> Efforts to formulate urban growth strategies

are especially interesting at the current time because they are in a transitional state. Problems of urban growth and development are on the verge of becoming privileged problems.

3. None of the central Governments concerned with these issues began to think in terms of such strategies until a wide range of specific and obdurate problems—of cities, within cities and between cities—had become highly visible. At first, they dealt with components of the problems, such as housing, industrial location, transportation, recreation and education. Only later did they grapple with the more basic problems of suburban growth and of the relationships between metropolitan regions and central cities. At approximately the same time, the problems of poverty and of lagging regions came to be treated as specific components of the larger, more complex problem of managing the economy. The efforts to limit the growth of cities and to promote the growth of lagging regions proceeded independently at first, by they eventually converged. This convergence was accelerated once the essential interdependence of these programmes began to be more fully appreciated. This, in turn, resulted in a quest for the elimination of inconsistencies, for more coherence and for more effective means of execution.

4. Extreme phases of the economic cycle, in particular, prosperity, also reinforced efforts to help lagging regions. This had not been true in the past. Until there was deep interest in the lagging regions, both prosperity and economic crises only diverted whatever attention was given to the problem. Once such interest emerged, however, prosperity and economic crises began to highlight regional discrepancies and problems of programming infrastructure investments equitably and efficiently. A modicum of political stability, a moderately effective civil service and some control or influence over capital allocations as well as tax policy sufficed to make the remedial efforts appear practicable. All that was necessary to spark action was the conviction of key decision-makers that they could do something to correct a serious imbalance and to produce more efficient or more socially desirable patterns of development. This sense of need and opportunity impelled the United Kingdom to ring London (and subsequently, other areas) with New Towns, spurred France to counter Paris with equilibrium metropolises, prompted the United States of America to confront the

<sup>1</sup> This paper is based on (and borrows extensively from) the relevant sections of Lloyd Rodwin, *Nations and Cities* (Boston, Mass., Houghton Mifflin Co., 1970). There are, however, also substantial additions to these materials as well as revisions of them.

<sup>2</sup> A. O. Hirschman, *Journeys Toward Progress* (New York, The Twentieth Century Fund, 1963), second and third paragraphs.

suburbs with urban renewal, led Venezuela to exploit its oil economy to foster the regional development of Guayana, and induced Turkey to try to offset the growth of the Marmara by encouraging urban development in other regions.

5. As this blend of circumstances is tantamount to a complex set of pre-conditions, the strategies evolved very gradually. This was not true in other related cases, such as in the relocation of a capital or in the decision to make massive investments to exploit the resources of a particular region. These were extraordinary responses to special opportunities or needs: some of these efforts, because they are massive, constitute national policies even if they are only implicit. But they do not necessarily lead to systematic, formal policies and programmes for the development of other cities and regions. In Turkey, under Mustafa Kemal and Inonu, they did not. The establishment of the new capital and the stress on urban development were important experiences and served as a reminder that new growth centres could be established. But the problem still had to be tackled afresh a generation later.<sup>3</sup> On the other hand, in France, the United Kingdom, the United States and Venezuela (and in Turkey, after the revolution of 1959), the adoption of national policies led to the creation of intellectual beach-heads, of administrative mechanisms and staff which could spread the essential ideas to strategic points inside and outside the Government. Over time, the increasing awareness of the commitments, the greater visibility of the policies and programmes, and the egalitarian pressures on Governments led to the extension of these policies and programmes. In all five countries, it took at least a generation before goals and policies were even roughly articulated; and it will take many years, perhaps another decade or a generation, before these ideas are translated into effective, systematic strategies.

6. None the less, one can expect a more rapid introduction of programmes to guide urban growth in the future, for most of the essential elements are now known. Whether one is concerned with policies, organizations or instruments, there are now a number of operating models. They offer a starting-point for thinking about a wide range of urban growth problems and of ways of dealing with them: the choice of goals and development alternatives; the administrative machinery; the incentive, control and review mechanisms; the inescapable constraints; and the appropriate relationships between development and planning agencies at different levels of Government. The existence of such models accelerates similar efforts elsewhere. This is evident by the speed with which underlying ideas are spreading. The notion of New Towns, basically British in origin, is now in vogue almost everywhere; and so are the ideas of urban renewal, an innovation of the United States, and of growth poles, a French doctrine, although none of these ideas were bruited about before the end of the Second World War.

<sup>3</sup> Cf. L. Rodwin, *op. cit.*, chap. 4.

7. The popularity of these ideas, however, is not at all a measure of their success. Actually, the difficulties encountered suggest that the problems of managing growth are formidable and are likely to evade easy solution. The United Kingdom has wrestled with some of them for more than a generation, and is only now perhaps on the verge of achieving its objectives. France began earlier, but it still has a long way to go—probably further than the United Kingdom—even though the formal administrative machinery in France appears more highly developed and the strategy of promoting equilibrium metropolises more explicit.

8. One could roughly rate these and other countries on the relative sophistication of their efforts on a number of counts: the adequacy of machinery to define development goals, not only aggregatively but by sectors and regions; the means that exist to co-ordinate development programmes by sectors and by regions; the explicitness of the basic urban and regional development strategies; the quality of staff and training programmes; the effectiveness of programmes enlisting contributions from the private sector; the linkages that exist among social, economic and physical elements; the capacity of local and regional organizations to handle their responsibilities; and the provisions for evaluation and improvement of performance as the programme continues. What is especially noteworthy is that, although such an examination would point up serious short-comings in each of these countries, it would also disclose that the concern in each country was with how to refine policies and to improve mechanisms, not with how to get rid of them.

9. In short, gaps in the understanding of theoretical and pragmatic relationships have not precluded the adoption of such strategies. On the contrary, when the need to act was agreed upon, then the disposition was either to experiment and to learn or, as Hirschman suggests, to follow "The Principle of the Hiding Hand"<sup>4</sup>—that is, to underestimate the difficulties or to over-estimate the benefits. In all of the cases studied, recourse to action on a significant scale sooner or later began to spur the necessary theoretical and applied research to sustain and extend these efforts. Moreover, because of the rapid spread of knowledge and experience, future experiments with development policies and programmes will acquire more of an adaptive character than an innovative one. This likelihood should further reduce the period between the initiation of such programmes and the development of more explicit, systematic policies and provisions for their implementation.

#### THE ENVIRONMENT FOR URBAN GROWTH STRATEGIES

10. France, Turkey, the United Kingdom, the United States of America and Venezuela differ in size, climate, resources and location. They range from small to large,

<sup>4</sup> A. O. Hirschman, *Development Projects Observed* (Washington, D.C., The Brookings Institution, 1967), chap. 1.

tropical to temperate, meagrely endowed to well endowed, and peripheral to central in their location. The five countries also differ in their institutions. Politically, they range from relatively centralized (France and Turkey) to relatively decentralized (United States). Socially, their cultures vary from relatively egalitarian (United States) to relatively hierarchical (United Kingdom). All have varying elements of homogeneity and heterogeneity, depending upon the criteria used for measurement. None of these differences have precluded the adoption of urban growth strategies, although they have influenced the effectiveness with which they were carried out.

11. The economies of these countries also differ widely. Some are poor, others rich; some are narrowly, and others widely, diversified. At the time they initiated their programmes, Turkey and Venezuela were in the take-off stages of industrialization; the others were highly industrialized and service-oriented. France, Turkey and the United Kingdom faced serious and immediate economic strains; the others did not. France had slow population and industrial development for more than a century; the others experienced the reverse. Both the more and the less economically developed countries are trying to spur national economic growth through the encouragement of growing regions. However, the economically advanced countries are also trying to arrest the decline of some regions, a decline stemming from changes in the location of industries, whereas the poorer countries are trying to induce development in primitive hinterlands. The lagging regions are prominent issues, particularly in the poorer countries, because of their magnitude and because a few of these regions may have very significant growth potentials.

12. These economic differences can affect urban and regional development strategies in fairly obvious ways. The most important involve the opportunities and constraints inherent in having relatively limited or relatively ample resources or in having a vigorous private sector and mature economic institutions<sup>5</sup> or the reverse. Another involves the differing psychological, as well as economic, significance of opening a *hinterland* rather than arresting its decline. What is intriguing, however, is that even though these differences have affected opportunities for development, they have not otherwise changed the main outlines of the urban and regional strategies adopted or the more general definitions of the problems on which they are based. Each of these countries believes it suffers from overconcentration in congested cities in some areas, underconcentration in others, and from undesirable and unnecessarily large regional differences in levels of social and economic development. All believe that they need to change the way the metropolis grows and to promote urban growth centers in the less prosperous regions.

<sup>5</sup> Examples are varied credit mechanisms and business and consumer services.

13. Institutional differences can be significant factors also. An urban growth strategy involves controls, incentives, and pressures to influence the scale and pattern of development of metropolitan regions. It requires priorities for regional development and measures to implement them. It means favouring a West or a North against an East or a South. Even if the measures do not go counter to dominant trends or powerful interests, they presuppose choices among alternatives which will shift costs and benefits for cities and regions and arouse stormy conflicts. Such policies ought to be easier to work out in countries with centralized Governments, hierarchical social systems and homogeneous cultures. In point of fact, they are—but subject to a number of important reservations. In a country with a weak local system of government, opposition to the central Government policy is crippled; but it is also harder to carry out the policy effectively in the field without able local or regional organs of government. The urban and regional aspects of growth strategy in Turkey and Venezuela betrayed serious weaknesses because of failings at this level.<sup>6</sup> On the other hand, a weak national system of Government is unable to develop a strong central policy for regional development, except through powerful incentives; relatively effective local, state or provincial governments; or a vigorous system of private enterprise. The existence of any or all of these conditions is exceptional. But they did prevail in the United States of America in the nineteenth century and were responsible, in part, for its development.

14. A hierarchical social and political system—where the governing class is accustomed to govern, where other classes are accustomed to acquiesce and where private interests have relatively less power—can more readily evolve urban and regional growth policies at the national level than systems under the sway of the market, local political jurisdictions or egalitarian political processes. This is one reason why urban growth policies burgeoned earlier in France and in the United Kingdom than in the United States.<sup>7</sup> But a hierarchical system—whether social or administrative, or both—has serious weaknesses in execution. It generally suffers from “apoplexy at the center and anemia at the edges”, problems that both France and the United Kingdom, as well as Turkey and Venezuela, are struggling to solve. On the other hand, if problems become serious enough (or simply appear to be serious enough), national strategies will emerge even in market-oriented environments. For example, the current furor over the problems of the central city in the United States, and, to a lesser extent, over the problem of energizing less prosperous areas, is prompting the Government to follow roughly the same course taken in the more hierarchical and centralized environments—

<sup>6</sup> L. Rodwin and others, *Planning Urban Growth and Regional Development: the Experience of the Guayana Program of Venezuela* (Cambridge, Mass., Massachusetts Institute of Technology Press, 1969); see also *idem*, *Nations and Cities*, chaps. 3 and 4.

<sup>7</sup> L. Rodwin, *Nations and Cities*, chaps. 5 and 6.

albeit with significant adaptations to take account of racial issues and differences in planning institutions.

15. All told, the adoption of variants of the same strategies in a wide range of different environments underscores the common problems and trends and conventional ways of thinking about these matters. Even more significant, perhaps, is the fact that in all of these countries, the common denominator is the conviction that the guidance of urban growth strategy cannot—or, rather, must not—remain only at the local level.

#### CONCEPTS AND GOALS

16. The urban growth strategies of countries are hardly mature, but one can already speak of a “traditional” approach to urban growth issues and of problems characteristic of this approach. It has become increasingly customary for development specialists to consider the role different cities and regions might or ought to play in the development of a country, and hence in the programming of infrastructure and in the shaping of industrial and other development policies. In France, the United Kingdom and Venezuela, this definition of roles has led to quite different decisions about development priorities, and such differing results comfort planners who want urban and regional considerations taken more explicitly into account.

17. None the less, there are difficulties imbedded in these ideas which need to be faced. Most planners, for example, are disposed to believe that development efforts will eventually founder if basic concepts are hazy and if development aims are obscure. Based on these assumptions, the future prospects of urban growth strategies rest on two “fuzzy” assumptions—the disadvantages of big cities and the feasibility of promoting growth centres—which no one to date has been able to define operationally. One does not really know when a city is too big or too congested, rather than merely poorly organized; and man has as yet learnt little more than the rudiments of how to convert an urban centre into a growth centre and how to radiate the effects of such growth centres over surrounding *hinterlands*. However, this is not the first time (and probably not the last) that decision-makers have to manipulate forces which they do not fully understand.

18. The situation may appear to be all the more discouraging because development aims are defined obscurely in most countries, and not just in the United States of America, whose aims have scarcely been formulated at all. The British goals, for example, of encouraging growth centres and reducing unemployment in the lagging regions are still so vague that they hardly provide an adequate basis for evaluating progress, or even for gauging how much of the changes in the character of urban development can be attributed to the measures undertaken. The French goals appear to be more explicit. The notion of equilibrium metropolises identifies the metropolitan regions where growth is to be encouraged and defines the strategy to

build up large cities to compete with Paris.<sup>8</sup> But conflicting national aims, not to mention pressures from other cities and regions, drain away much of the substance of this policy, so that in France, too, it is difficult to say what level of performance would represent satisfactory progress in carrying out its strategy within a reasonable period. The objectives in Turkey are far vaguer still. There are no explicit commitments, only general intentions of encouraging growth centres and correcting imbalance between growing and lagging regions. Plans are prepared which are supposed to be backed up by the Government of Turkey and by private investments in the designated regions; but, more often than not, this fails to occur.

19. The sole exception, perhaps, is the experience of Venezuela. Plans for Guayana were incorporated into the national plan, and specific, staged targets for regional investment, production and exports were linked to plans for national development. But this was true only for the Guayana region.<sup>9</sup> Indeed, the success of Venezuela's policy was possible only by focusing on one region whose development had national significance and by systematically exploiting the unique resource endowment of the region with relatively ample capital resources. Even under these highly favorable circumstances, the projected targets aggregated many important elements and were meaningful and well-implemented only in comparison with the way regional plans were prepared elsewhere.

20. The experiences of these nations indicate the ambiguity and the range of variation that might be expected in the definition of aims in the early years of such a planning venture, and perhaps for many years thereafter. They suggest that it may be impossible—at least at the outset—for a government to formulate adequate or precise national goals for urban and regional development. What appears to be a far more feasible approach is the preparation of some general guidelines which can later be successively redefined. It may also be possible to work out somewhat more adequate and more detailed development goals and programmes in one or two regions. These can then be tried and evaluated and serve as a training ground and as a guide for efforts elsewhere.

21. Of course, it is more customary, and attractive, to argue that clear goals should be set from the start. But this does not appear to be an option. It is very hard in the early stages to devise solutions to complex problems or to obtain backing for new ways of dealing with them. However odd it may seem, it is easier and often more realistic to fix precise goals in the middle or towards the end of a programme. Effective goals

<sup>8</sup>J. Hautreux and M. Rochefort, *La fonction régionale dans l'armature urbaine française*, Commission nationale de l'aménagement du territoire (Group V), Commissariat général du plan et direction de l'aménagement foncier et l'urbanisme (Paris, Ministère de la Construction, 1964); see also P. Baucher, “La comptabilité économique régionale et son usage”, *Economie appliquée*, vol. 14, No. 1 (1961), pp. 71-74.

<sup>9</sup>J. Friedmann, *Venezuela: From Doctrine to Dialogue* (Syracuse, N.Y., Syracuse University Press, 1968).

presuppose awareness of what is feasible and desirable. They are, in effect, the fruition of much thought and experience and substantial consensus. This implies a learning process, often stretching over a decade or two. During this period, however, vague formulations and limited efforts, for all of their inadequacies, serve a useful purpose. They indicate general directions and invite the necessary initial critiques and refinements of goals and methods. In the course of these efforts, the bureaucracy and the public are given time to familiarize themselves with the issues and time to devise ways and means of dealing with unsuspected difficulties, or of avoiding further entanglements.

22. Despite the relatively obscure objectives indicated in the cases mentioned above, the kinds of measures deployed in these different environments have been fairly limited. The principal ones involve changing the rate of growth of a major city and encouraging development in growth zones within metropolitan regions and in other areas. The traditional instruments for these purposes range from controls to a variety of development schemes and incentives for public and private investment programmes.<sup>10</sup> Of course, it makes a difference how these measures are applied: whether there are many loop-holes in the controls, whether the incentives are significant enough to induce the desired outcomes, whether all or only some of these instruments are deployed, whether the diverse efforts are made by one organization or by several, whether the policies are reinforced by other policies and programmes of the national Government. The pattern to date—in France, the United Kingdom and the United States of America, and, to a lesser extent, in Turkey and Venezuela—is for simple, limited measures to be initiated at the outset, out of prudence and ease of innovation and possibly also out of lack of conviction or clarity either about the goals or the efficacy of the means.

23. This prudence is understandable. With a relatively new policy where it is difficult to foretell the problems that may be encountered or the consequences of policy choices, the best the decision-maker can do in the beginning is to develop simple analytical and administrative machinery that may be made more efficient with time and to avoid major and relatively inflexible commitments until there is more of a consensus, or until the decision-maker is more certain about what is likely to happen. Later, as goals become clearer and if they still seem worth pursuing, he can

<sup>10</sup> The development schemes are mainly investments in infrastructure, industrial estates or joint (public-private) industrial or business ventures. In the main, the incentives to induce private activity take the form of one or more of the following: tax bonuses; inexpensive credit; accelerated depreciation; cash grants; employment; or transportation premiums and exemption from exchange or import restrictions. As noted later in the paper, it is generally essential to have both controls and incentives. Tax incentives and infrastructure investments (particularly in transportation) reinforced with a vigorous public development and land acquisition programme have generally proved to be the most effective combination of measures to implement agreed-on urban development strategies—in countries with reasonable administrative capability.

either improve the tools (tighten or extend the controls, enlarge the premiums, change the definition of areas, perfect the co-ordinative mechanisms) or devise new tools to make the efforts more successful. He may also decide that the aims are wrong, or more probably, that they could be realized more efficiently by still other means; in that case, he might relax controls and place more reliance on other tools, such as the price system.

24. This orientation today towards more controls and larger subsidies is all the more striking since, as have been observed, the experience with controls and incentives has been until recently somewhat disappointing. They have generally proved to be inadequate as a means of reversing a powerful force such as the expansion of a capital or a dominant metropolis. The opportunities for evasion are legion and the strain of enforcement on the administrative apparatus is severe. In France and the United Kingdom, after a generation of effort, the controls and incentives are working better—but still not adequately. The principal justification for controls and incentives today is not that they prevent congestion or successfully induce new growth. It is rather that in a territory containing several development possibilities, a well-designed system of controls and incentives will prompt many firms and ministries to take advantage of these other possibilities.

25. A national system of incentives and controls to reinforce an urban growth strategy can be evolved in many ways. One possibility is to begin at the top, create an intelligence unit close to the chief executive and then develop a national strategy for area development. This is doubtless the most appealing approach from one point of view, for it is certainly possible now, in principle, for a small group of specialists to devise a fairly comprehensive strategy: to spell out goals; to write legislation; to formulate policies; to fashion administrative mechanisms; and to devise means to carry them into effect. Doubtless, this can be done all the more quickly and elegantly if there is a national planning organization. But unless there is a large backlog of experience on these matters, not to mention adequate staff and resources, such efforts are apt to bog down. The ideas will not be fully understood and therefore will not gain the necessary backing in different quarters, especially in the local regions. The programmes in the United Kingdom, the United States, Venezuela and even France did not evolve in this way; and the brief experience of Turkey with planning from the top down suggests that when such an approach is followed, it will not be effective.<sup>11</sup> However simple and direct the centralized style may appear, the lack of an adequate analytical, administrative and political base outside the political centre often turns out to be a crucial weakness. It would take a rare group of administrators, indeed, to overcome it.

26. An alternative approach is illustrated by the experience of Venezuela or by the later stages of the

<sup>11</sup> L. Rodwin, *Nations and Cities*, *op. cit.*, chaps. 3-7.

regional planning programme in Turkey. In these two cases, the emphasis was on promoting one or more metropolitan regions; at the same time, or at some reasonable period thereafter, these programmes were linked into national development plans and policies. This approach built up the necessary experience and trained staff and gradually familiarized key elements of the public and the Government with the programme and the issues. A basic assumption here is that the essential ideas of the programme have merit and will win further support, that they will survive despite inconsistencies and conflicts between regions and that over time they will generate pressures for complementary programmes.

27. Despite the clarity of the goals of a country, political pressures can complicate and dilute the effectiveness of development policies. The issue of dispersal or concentration is an illustration of this. In the past, and even today, the pressure to satisfy political requirements hobbled programmes in France, the United Kingdom and the United States of America (not to mention Italy and other countries in western Europe). Dispersal was more effectively resisted in Venezuela, due to a political leadership which created an extraordinary national consensus about an exceptional region; and it was also successfully resisted in Turkey under the leaderships of Kemal and Inonu, but not thereafter. In general, however, the free market tends to favour concentration, whereas making the issues explicit often tends to consolidate political pressures and to favour dispersal. Thus, the great task of urban statesmanship is to develop the necessary political imagery to steer a middle course for a reasonable period in the future. This task, however, is extremely difficult. To date, the issue of dispersal or concentration has proved so inflammatory and the way it is resolved so critical to the success of any policy of development that Governments have often found it necessary to talk one way and to act another. And although it is easier politically to advocate dispersal and then allocate resources otherwise (or allow such allocations to occur), the experience of France suggests that, on occasion, this process may be reversed. There, "lip service" has been paid to the ideology of concentration, but, as yet, this has imposed very few constraints on a far more permissive allocation policy.

#### SOME CAUTIONARY INFERENCES ON POLICY IMPLICATIONS

28. Given these broad trends, one may ask what specific inferences might be ventured for decision-makers pondering these issues. For discussion purposes, seven propositions warrant further consideration. These propositions can be cast in the form of cautionary observations, which, if the evaluation of these experiences is sound, ought not to be lightly disregarded by anyone concerned with the formulation of policy on these matters.

29. The seven propositions are discussed below.

30. The first proposition is that, for the next generation (15-20 years), it is probably not feasible (or desirable) in most developing countries to stop the spread or the growth of population of the giant cities (cities with population of 500,000 or more); but it may well be feasible (and desirable) to lower their rates of growth in relation to the growth rates of other urban centres.

31. To the best of the author's knowledge, there are no examples of successful efforts to stop the growth of these giant cities or to reduce their size. The Union of Soviet Socialist Republics failed to curb the growth of Moscow; Mussolini's system of entry permits proved of no avail in arresting the growth of Rome. The United Kingdom failed to stop the growth of London. France—with the most highly centralized bureaucracy in the western world—has not been able to curb the growth of Paris. In most giant cities, the central cities may be growing less rapidly or even losing population; but their outer regions are expanding enormously. Given these deep-seated and pervasive trends, there are scarcely any persuasive grounds for thinking that developing countries will prove more effective in coping with these problems. All the evidence suggests they have neither the administrative capability nor the resources, not to mention the will, to succeed in this extraordinarily difficult enterprise.

32. One can be a bit more sanguine, however, if the goals are more modest. Thus, it may be possible to increase the income and number of jobs in other cities and regions, and to improve their infrastructure and enhance their growth capabilities. Some examples exist of progress along these lines: witness the transformation of the western part of the United States of America in the nineteenth century, induced by an extraordinary system of incentives and infrastructure investments; and the similar transformation in the twentieth century of the Soviet Union east of the Urals, or the development of Ankara and the interior of Anatolia in Turkey, all of which have resulted in a far more balanced system of cities than otherwise would have been the case in these countries. Similarly, in western Europe in the past generation, there has been increasing sophistication in the efforts to encourage growth in the less prosperous regions of the United Kingdom, in promoting regional equilibrium metropolises in France to offset the growth of Paris, and in encouraging the relative increase of income and the growth of economic activity in the south of Italy—to cite only a few examples. Although none of these (and other) efforts are unequivocal success stories—judging from the controversies concerning the incidence of their costs and benefits—they provide some evidence that more modest objectives are or may be obtainable, and perhaps even with reasonable costs.

33. The second proposition is that fostering big cities is one of the best means of countering the growth of the giant cities. Small cities cannot fight giant cities. It is an unequal match and they are sure to lose. Firms in the giant city have a larger and more diversified

manpower pool. Families have more varied and diversified job and cultural and social opportunities. Both firms and families have access to superior business and consumer services. Giant cities concentrate population and income; and they reinforce the habits, the attitudes and the tempo of modern society. They can command critical managerial skills, and they can display a wide variety of role models likely to spark worldly ambition and competitive effort. Most small cities which compete with giant cities do so only when they are within and part of the metropolitan region and can tap all of the advantages of that region while avoiding most of the costs.

34. Existing large cities (those with populations ranging roughly between 100,000 and 500,000)<sup>12</sup> or new large cities can muster more effective resources to compete with the giant city. A small city which loses a few of its economic activities is in a perilous position. A large city, like a large corporation, can use its assets and services to reorganize and transform its economy, its infrastructure and even its environment. A big city can better organize and finance the necessary intelligence functions and development organizations to evaluate its problems, its resource endowment, and its needs, aspirations and development potential. Perhaps the two most dramatic illustrations of this fact today are: (a) the changed emphasis of the second generation of British New Towns in the direction of larger size and their use as economic weapons to accelerate growth and reduce unemployment in the north of the country; and (b) the recognition by the French Government of the urgent need to promote regional equilibrium metropolises and regional intelligence mechanisms. Such actions alone may be insufficient, but they are surely a step in the right direction.

35. The third proposition is that New Towns and expanded towns should serve, rather than ignore or frustrate, the basic aims of settlement strategies. New communities can easily become a retreat from the problems of the central city. Such new communities are expendable luxuries. Their social value is marginal if they do not specifically reduce the diseconomies and improve the organization of the giant cities or encourage growth centres in lagging regions, especially those with a large unemployed and underemployed population. But these ends will get short shrift if the focus is mainly on the building of one or several New Towns and not on the basic settlement objectives. Most New Towns partisans are so intrigued by the challenge of building new and planned communities that they overlook the fact that any projection of likely New Towns to be built will show that the number is not going to be large and the population to be accommodated will serve only a tiny segment of relatively well to do members of the population. In addition, the research and innovative

aspects of New Towns are apt to be greatly exaggerated, particularly as the pressure to make them successful drives out high-risk activities and provides powerful reinforcements for conservative judgements as to what innovations will work.

36. Unfortunately, it is not easy to relate new communities either to the immediate or to the long-term needs of the giant metropolis. Most planners and developers think their problems are harrowing enough without having to take on the burdens of existing cities or the problems of depressed areas. What is more, it would be quite a feat to develop a significant programme in which costs are shared nationally, but the visible benefits to particular regions are sharply limited. Certainly, it is much easier to build new communities in high-growth areas where the market prospects are more attractive and interest in innovation (in urban design, transportation and building methods, or in novel health and educational services) is more deep-rooted.

37. Fourthly, if a policy of concentrated decentralization is pursued, the choice of regions is of critical importance and should be related to the goals, constraints and development opportunities, with special concern for equalization and spread effects. Although political considerations will doubtless shape the final outcome, decision-makers need helpful criteria to guide the choice of regions for development—if only to suggest the kinds of compromises that might reasonably be made. Undoubtedly, any extensive development planned for selected regions will take a number of years to promote. Therefore, while tentative programmes may be initiated, based on existing knowledge and pragmatic judgements, more detailed studies can be gotten under way. Then, at some subsequent stage, when one has acquired a better sense of development prospects, these programmes and their planned sequences can be reviewed and either stepped up or contracted. For a variety of reasons, however, the decisions in both the short and long term will be influenced by the relevant goals, constraints and development potentials.

38. Most countries want to maximize growth rates and to increase *per capita* income. But these general goals are subject to a variety of constraints.<sup>13</sup> Some of the more important of these are: minimum levels of consumption; implicit discount rates of future returns; desired distribution (or desired rate of change in the distribution) of income by class and region. Other restrictions emerge from projected defense requirements and from the need for internal consistency in resource allocations, such as specified exchange balances and execution of programmes within available or potentially available resources of capital and of managerial and administrative ability. An even more important limitation today may be a preference for certain ways of carrying out programmes, such as emphasis on, de-

<sup>12</sup> For a comparable estimate, see N. M. Hansen, ed., *Growth Centers in Regional Economic Development* (New York, The Free Press; and London, Collier-Macmillan Limited, 1972), pp. 278-279.

<sup>13</sup> The difference between goals and constraints is often moot or meaningless. See R. Dorfman, "Operations research", *American Economic Review*, vol. 50, No. 4 (1960), p. 609; and J. Margolis, "The evaluation of water resources development", *ibid.*, vol. 49, No. 1 (1959), pp. 99-100.

centralization and participation as well as on system maintenance.

39. Studies of market areas, urban hierarchy and metropolitan *hinterlands* also underscore the function of urban growth regions as innovative and economic seedbeds for much larger *hinterlands*. This suggests another important consideration, namely that the region(s) selected for further development should be those which, with relative economy, could improve their access to large, resource-rich or densely populated *hinterlands*. To apply this criterion, evaluations would have to be made of the probable cultural and economic consequences of proposed development programmes in different regions. In particular, these evaluations would have to consider the number of families affected and the likely changes in consumption and saving patterns and in social and other relationships. To be sure, few of these changes can be traced with precision. But, if an essential aim is to transform traditional attitudes and values, it is important to estimate how effectively different regional developments serve this end.<sup>14</sup>

40. Almost needless to say, more refined comparative analysis of the problems of the long-term prospects of the leading regions will also be essential in order to evaluate development alternatives and to make programme recommendations. This would presuppose evaluations of the principal characteristics and capabilities of the population. It would involve projections of trends in the main economic activities, in population, income, investment and consumption. Knowledge of the demand and supply implications for related activities in the "leading regions" would also be necessary. It would be useful, too, to try to estimate the probable impact of existing national development policies on sectors within the selected regions, as well as the induced effects of the regions' development on the national economy. Where data and circumstances permit, even the currently inadequate and unrealistic interindustry and interregional input-output matrices and programming methods might be employed, if used mainly to direct attention to interacting relationships and significant implications which might otherwise be overlooked.

41. The fifth proposition is that although encouraging concentrated decentralization in large cities may be a reasonable policy given the current state of knowledge, it is politically defensible only if there are appropriate complementary efforts to assist other problem regions. No matter how justified it might be economically to follow a policy of concentrated decentralization, such a course of action appears to be, and perhaps it even is, essentially unfair and inequitable. There is something fundamentally unjust about the Government helping some areas and neglecting others. Even confirmed pragmatists might balk at a policy of apparent

favouritism—sanctioned though it might be by the biblical precept: "To him that hath shall be given". This may be accurate prophecy; and it could well contribute to greater productivity. But in an age when the prevailing ethic favours egalitarian perspectives, it is dangerous and often nearly impossible politically to follow such a course.

42. The question is whether this means that such a policy is essentially non-operational and impractical. The answer is: not necessarily. There are ways one might invest resources which may be politically prudent as well as economically wise.

43. With a little imagination, means might be devised to help people in non-growth regions while mounting major regional programmes elsewhere. The population of regions not likely to respond to and therefore not destined to receive significant economic investments ought to obtain alternative forms of assistance consistent with this policy. By means of agricultural and community development projects, land reform and self-help schemes, migration to larger cities may be reduced to somewhat more manageable levels. It might also be possible to organize (and perhaps even to subsidize sufficiently the cost of) transportation to bring many families living in lagging regions within reasonable commuting distance of growth centres. Much could also be done to ease the shifts of population that must occur. Training programmes could be set up, accurate information on expanding areas disseminated; and, where resources permitted, minimum assistance payments provided during the period of relocation. Investments in health and education, in social rather than in economic overhead capital might also be emphasized in these regions.<sup>15</sup> Such investments would contribute to development as well as to welfare. Lastly, some areas might only need help for a short period or might require more moderate assistance, whereas in other areas some uneconomic investments and tax bonuses might be inescapable. In short, some positive and some token efforts and a great deal of consummate political skill are essential. Success would depend upon the balance struck between economic progress and social welfare, and upon a sensitivity to those repercussions which can upset a theoretically rational development programme.

44. The sixth proposition is that national strategies for urban development will be seriously handicapped until the resources and capabilities of local governments are greatly strengthened. Currently, almost everywhere, local revenues are hopelessly inadequate, pay and staff poor; and local services in education, transportation, housing, recreation, social service and basic information in need of massive improvements. There are several reasons why the problems of local capability have not played a major role so far in national policy in relation

<sup>14</sup> For some suggestive notions on the effects of regional developments on traditional attitudes, see D. Lerner, *The Passing of Traditional Society* (Glencoe, Illinois, The Free Press, 1958), chap. 1; and L. R. Peattie, *The View From the Barrio* (Ann Arbor, University of Michigan Press, 1968), chaps. 10 and 11.

<sup>15</sup> See N. M. Hansen, "The structure and determinants of local public investment expenditures", *Review of Economic Statistics*, vol. 47, No. 2 (1965), pp. 150-162; and N. M. Hansen, *French Regional Planning* (Bloomington, Indiana University Press, 1968).

to urban growth strategies. In the poorer countries, central Governments have been in no position to transform local government services; nor have these problems been as pressing in the short run as the monetary, exchange, general development or minority problems which have faced the central Governments. Moreover, in most of these countries, there exists no tradition of strong local government. Often, there are powerful landed or regional interests—vestiges of feudalism—which the central Governments are trying to combat. These conditions, coupled with meagre resources and inadequately trained professional staff, have made it unlikely for central Governments to have either the capacity or the desire to strengthen local or regional independence. But overloaded central staffs, and the need to stir local initiative, will eventually spur efforts to solve these problems through some form of decentralization.

45. In the more developed countries, such as France, the United Kingdom and the United States of America, the local governments had, or have acquired, greater responsibilities for territorial planning and development. But even these powers have proved inadequate. The mounting obligations accompanying increases in population, in welfare services and in development responsibilities have compelled persistent efforts on the part of national Governments to strengthen local capabilities. During the past generation, these efforts took the form of matched grants from the central Government for specific services. The current trend is towards enlarging local government boundaries, as in France and in the United Kingdom and towards providing unrestricted block grants to local communities, as in the United States.<sup>16</sup>

46. One effect of these measures will be the weakening of the power of the central Government to guide developmental strategy within the region. If communities do not require financial assistance, they will not be especially receptive to unpopular national policies. However, block grants and changes in boundaries will not alter the need for national efforts to induce desired changes in interregional or intraregional patterns of development. Therefore, national incentives are likely to be increased in order to aid lagging regions, to underwrite urban renewal, to siphon off population growth

<sup>16</sup> See, for example, Royal Commission on Local Government in England, *Written Evidence of the Ministry of Housing and Local Government* (London, HMSO, 1967), especially part 2; *Written Evidence of the Department of Economic Affairs* (London, HMSO, 1967), pp. 1-4; United Kingdom, Department of Economic Affairs, *Minutes of Evidence*, 19 January 1967 (London, HMSO, 1967), pp. 3-20; Ecole nationale d'administration, "L'Adaptation de l'organisation administrative française aux problèmes d'aménagement des grandes agglomérations urbaines", seminar directed by P. Voit, Chief of the Urban and Regional Division at the Commissariat Général du Plan, Paris, March 1966, pp. 19-46 (mimeographed); Centre de recherches et de documentation sur la consommation (CREDOC), *Etude méthodologique sur les programmes d'équipements urbains réalisés à ce jour* (Paris, 1961); and V. Bourrel, *Rapport de la Commission d'étude des finances locales à M. le Premier Ministre* (Paris) Imprimerie nationale, 1965).

and industries from congested areas and to support other programmes favoured by the central authorities.

47. The seventh proposition concerns a basic question confronting urban development strategies, that of the way in which to ensure that the groups who should benefit from growth shall actually do so. Providing assistance from the affluent regions to the poorer regions by way of the central Government often ends up with the giver as the principal beneficiary. It has therefore been urged that regions, and in particular the people of these regions, be given a greater voice in the administrative and political process. Mainly dissident minorities have expressed these views to date, but the ideas reflect the mood of the age and are neatly attuned to prevailing circumstances. It is hardly surprising that they are spreading and bid fair to become the conventional wisdom of the future.

48. One can see these tendencies in a number of different political and social contexts. For example, in the Guayana region of Venezuela, the dissidents stressed the importance of having the Guayana Development Corporation consult the views and needs of the local population—the merchants and political leaders and even the humbler elements of society. They wanted a greater emphasis placed on achieving high employment than on attaining a high rate of growth. They favoured low density, more self-help and owner-occupied housing in places where migrants could find jobs and learn more easily about new opportunities. They objected to the criteria used for housing selection and welfare, which some of the local population considered to be inappropriate for many of the families the programmes were intended to serve. A growing awareness of the discrepancy between the needs of the population and the policies of the administrators soon led some of the local leaders to explore ways of effecting change by pressures and other processes and even by violence.<sup>17</sup> Ultimately, on some matters, such as the distribution of public land to the local community, the Guayana Development Corporation was forced to reverse its position in response to the pressures of the local leaders.

49. Other national programmes have also been modified by local demands. In Turkey, despite the disdain for local views and a highly centralized administrative tradition, local and regional pressures have forced more attention to be paid to development in the eastern region, though "participation" is still a long way off. In the United Kingdom, on the other hand, the claims for regional autonomy in Scotland and Wales have been asserted with increasing intensity. In France, even more than in the United Kingdom, the emphasis has changed from simply helping the lagging regions to providing more opportunity for their participation in the decision-making process. These views, expressed often enough before the political disturbances in May and June of 1968, were clearly a reaction to the paternalistic

<sup>17</sup> L. R. Peattie, *op. cit.*, chaps. 6 and 7.

and heavy-handed tutelage of the French administrative process. For a long time, they were dismissed as contrived political pressures encouraged by an intractable opposition; but after the events of May and June, and even after the subsequent elections which gutted the opposition, the Government radically reversed its position and supported the creation of regional assemblies as well as a gradual movement towards eventual fiscal autonomy. Moreover, the Government favoured these measures on the grounds that the people in the regions would thereby be more apt to pursue vigorous measures in their own behalf.<sup>18</sup>

50. As for the United States of America, although its long-established pattern of decentralized state authorities has been dwindling in importance, new pressures for more local control have arisen from certain militant leaders of the poor and the black. Only such power, it has been contended, will allow vigorous efforts in self-improvement, and only the possession of such power will transform the black population's image of itself and of its status. These views have come to the

<sup>18</sup> L'Equipe de la Revue "2000", *Essai sur la participation, autonomie, et solidarités*, No. 9, "Special", Paris, June 1968. See also the remarks of the former Prime Minister Couve de Murville and General de Gaulle, cited, respectively, in *Le Monde*, 15-16 December, 1968, p. 6; and 4 February 1969, p. 2.

fore at approximately the same time that several experiments have been undertaken to encourage "maximum feasible participation" by low-income families in a variety of economic development, educational and housing assistance programmes designed to help them improve their conditions. The ambiguity of the language and the inadequacies of certain programmes have led some persons to dismiss such efforts as impractical and misguided. But it is far from certain that the programmes have failed or that their limitations have been due to inherent weaknesses rather than to inexperience and limited resources.<sup>19</sup>

51. In any case, the evidence seems to suggest that, in the future, urban growth strategies will not be simply efforts of the central Governments to aid lagging regions through incentives and controls. These strategies will be characterized by pressures and demands on the part of the populations of these lagging areas and their supporters for a greater share in the planning and administration of policies.

## COMMENTS ON "NATIONAL POLICIES AND EXPERIENCES RELEVANT TO URBAN DEVELOPMENT: AN EVALUATION"\*

*Kazimierz Dziewonski\*\**

1. Generally speaking, this author is in complete agreement with the seven points on policies for urban and rural development as formulated by Lloyd Rodwin,<sup>1</sup> although for different reasons and sometimes even for opposite ones. The last part of the foregoing statement should not really surprise anybody as the author comes from a country of different social and economic formation and structure, as well as of varying cultural traditions. More surprising, perhaps, is the first part about the complete agreement based both on theoretical reasons and practical experience. Nevertheless, some of the points raised should be amplified. However, at the very beginning, an additional, wider problem should be raised, which, although a little theoretical in formulation, is indeed essential but was omitted by Professor Rodwin.

2. The development policies pertaining to settlement should consider and be directed towards the whole settlement system and not only a single type even though that is the largest class and type of settlement. These policies should be complex and comprehensive. The term "settlement system" is used in this statement in preference to the term "settlement network" to stress the fact that all settlements in any country are interdependent, rather than a purely accidental, random collection of urban and rural settlements, of cities, towns, villages, hamlets or even single farms and homesteads. However, in some countries, specifically in the developing countries, which have only recently gained their national independence, the settlement system may be not fully integrated. It may consist, in fact, of several varying systems, one superimposed upon another. These were created by different social and economic formations, tribal, feudal, capitalist and so forth, as well as by varying national and religious cultures, civilizations and traditions. The national system in these countries is usually composed of at least two not fully integrated systems, one tribal, i.e., local and regional, and the other supranational, representing the rejected colonial economy and society. One of the difficulties in such cases is that, on the one hand,

the older, traditional systems represent an antiquated, obsolete economy, while, on the other, the inherited colonial system is the only one functioning at the national level. In such situations national settlement policies have to accept as one of the main goals full integration, in fact the creation of a new national settlement system. But in all cases, with a growing society and economy, some changes in the national settlement system are inevitable; and as all settlements are interdependent, they should lead to a balanced and stable structure for the whole system.

3. To change or to steer and direct changes in a settlement system is not an easy task. The systems, especially in their physical or spatial aspects, are fairly stable, representing in their infrastructures the accumulated efforts and labours of past generations. Sudden, radical changes involve the expenditure of rather large funds that are often difficult to obtain. In most cases the changes are differential in character and slow in time. They need careful steering and long-term, stabilized policies. They have to take into account also some natural, spontaneous trends and the transformation of existing conditions, forms and patterns.

4. Along with the basic, strategic goal of settlement policies which is to obtain an integrated, stable and balanced settlement system, there may be also, indeed there should be, adopted some partial, tactical, short-term additional goals. These goals should be concerned with either specific types or classes of settlement or with individual regions, which play or are to play a leading, dominant role in the transformation and integration of the whole system. In such cases, it is important that the final, strategic goal, the integrated and balanced system, is fully envisaged and constantly kept in mind. The tactical aspects of the temporary, sometimes *ad hoc* and changing short-term policies should not be forgotten either.

5. To develop these parallel, long- and short-term policies, there is a need to define strategic and tactical or operative goals. To adopt proper means for their implementation, it is necessary to identify early in the process both the various superimposed systems in need of integration and the various settlement subsystems, either regional or functional. Among these last, at least three may be mentioned: i.e., large urban agglomerations (called by Professor Rodwin "giant cities"); central places of regional importance (in Professor Rodwin's

\* The original text of this paper (E/CONF.60/SYM.III/29) was submitted to the Symposium on Population, Resources and Environment, Stockholm, 26 September-5 October 1973.

\*\* Deputy Director of the Polish Academy of Sciences, Warsaw.

<sup>1</sup> See Lloyd Rodwin, *National Policies and Experiences Relevant to Urban Development: An Evaluation*, above.

terminology: large cities); and, lastly local urban-rural settlement complexes (containing small or market towns, villages and other smaller rural settlements).

6. On the first point pertaining to the growth of "giant cities" or large urban agglomerations, two aspects, arising out of Polish experience, appear to be worthy of mention. In general, people migrate in search of either employment, perhaps better employment, or improved living conditions, particularly as expressed by better services (in trade, health, education or cultural life). Urban agglomerations always present many opportunities of alternative employment; but, also, being overcrowded they are less attractive from the point of view of living conditions. This may explain the fact which should be noted here, that in practically all developed countries large cities currently grow at a higher relative rate than the so-called "giant" ones. For the same reason, it is easier to steer the growth of such large urban agglomerations by controlling employment than by administrative restriction on the influx of new inhabitants. In reality, it is the only really effective way. Moreover, the alternative of administrative control over the settlement of new inhabitants within the city leads to some negative social phenomena, such as corruption of officials and a black market in housing.

7. Deceleration in the growth of urban agglomerations is therefore possible, but it may easily lead to difficulties and disproportions in the over-all demographic urban structure in the form of a quickly aging population, unable even to reproduce its current number. In conditions of growing economy, a major goal of all national and international policies, does one want to have the largest urban concentrations of population with an aging structure, unresponsive to the challenge of modern technologies, more conservative in its outlook and way of living than, on average, the over-all population of the country? This question is, really, rhetorical. The answer has to be negative.

8. So far as Professor Rodwin's second point is concerned, pertaining as it does to the growth of large cities, the regional centres, the present author agrees with him entirely. It seems useful to add here only one observation. The regional centres usually play four differing, although complementary and mutually dependent, roles. These are administrative capitals of specific regions, centres of production and services for the surrounding area (central places in the meaning of W. Christaller's theory), points of concentration for nationally specialized processing industries and important centres for the diffusion and spread of scientific and technological as well as of cultural and social innovations. For the full success of policies directed towards fostering their growth and development, these roles should be constantly kept in mind and provided for in all plans or development programmes. In specific conditions—it is true—the role of a regional centre may be split between different localities; but in such cases, the creation of a strong, quickly growing regional centre and a large city becomes more difficult and involves

additional care in planning and programming, as well as in the selection of means for the implementation of adopted policies.

9. The problems of New Towns and the advisability of pursuing the policy of their construction were thoroughly discussed during the United Nations Seminar on New Towns, which was held in London in June 1973. The results, although obviously more detailed, were in complete agreement with reasoning of Professor Rodwin.

10. The present author agrees also with his opinion on the critical importance of the choice of regions in the strategy of concentrated decentralization. The way the growth of a large city will stimulate and spread the economic development throughout the whole regional territory has to be studied carefully and planned wisely indeed.

11. The need for complementary efforts to assist other problem regions and to take into account all settlements and their problems is inherent in the very concept of settlement system. Therefore, no further comments need be added to the fifth point made by Professor Rodwin.

12. The need for strong local government for the full success of settlement policies is crucial and in reality cannot be stressed too much. However, this point should be broadened by including among the partners not only the local authorities, but the local community. Other reasons also exist. The policies of the central administration sometimes undergo very sudden changes, or, at least, there are some vacillations in their implementation. It is the role of the local community and authorities, as representing the social consciousness and public opinion, to insist and to defend the carrying through of an adopted solution right to its conclusion. In addition, without the understanding and adoption of the planning goals and aims by the local community, these may easily fail not only because of silent opposition, but solely through lack of proper support.

13. Equally important is the point that benefits of urban development should reach those social groups for which they were intended in the beginning. This is a very difficult task involving constant observation and control of the plan implementation.

14. Among the points made by Professor Rodwin, some recommendations are missing pertaining to the rural (or rural-urban) settlement. There is a very strong interdependence between changes taking place at the level of largest cities and urban agglomeration and those among the smallest settlements, i.e., villages and small towns. On one hand, in most cases, progress in agricultural production and the well-being of rural population involves serious reduction in the number of persons living in the countryside; and this process may be easily carried too far bringing about the complete depopulation of these areas. On the other, cities grow by immigration—the rate of natural increase being there rather low. The influx of the rural population is needed for their development. If it is cut off, the negative phenom-

ena already mentioned may well develop. The influx may be and, in fact, often is too large, taking place before a sufficient number of jobs and dwellings have been provided. Evidently, the process of migration has to be planned and directed at both ends, in the countryside and in urban areas.

15. Changes in the rural and rural-urban areas also involve the resettlement or at least the regrouping of the population. The communities involved being small and dispersed, it is easy to propose very radical, but not well thought-out solutions. In large cities changes, of necessity (because of their size and complexity), are evolutionary and are conceived as such. With rural settlements, the need for evolutionary measures is often forgotten. However, it is very important, indeed essential.

16. The main problem to be decided on is the measure of either necessary (and possible) concentration or desirable (and feasible) dispersal in settlement. There is no doubt that the technical solutions (agricul-

ture, technology, sanitary equipment, services), favour concentration, but farmers and peasants usually prefer dispersal. The chosen solution, which for various countries, climates and civilizations will probably be very different, may well depend upon the degree in which the urban way of life spreads and is adopted by the rural (agricultural and non-agricultural) population.

17. Returning to the main point of the remarks made in this paper—the importance of interdependence between various settlements whether taken by classes and types or individually—it is appropriate to recall the well-known saying of John Donne, made famous by Ernest Hemingway, who used part of it for the title of his best novel:

“Any man’s death diminishes me, because I am involved in Mankind;

“And therefore never send to know for whom the bell tolls; it tolls for thee.”

18. For human settlements, it is true not only in death, but in life.

# THE COSTS AND BENEFITS OF ALTERNATIVE SETTLEMENT PATTERNS \*

Harry W. Richardson \*\*

1. This paper explores the question of socially desirable patterns of human settlement from the point of view of growth, equity and environmental objectives. There is little evidence to support the hypothesis that minimizing the use of natural resources would lead to particular spatial distributions of population; and, therefore, much of the attention is given to the narrower problem of whether large cities generate negative net externalities as a result of environmental disruption and quality of life deficiencies. The answer to this question is the prime determinant of the need for and scope of a national population distribution policy, though it is clear that such a policy would be concerned with much wider aspects than the control of city size. The gist of the argument is that the optimal city-size concept is a chimera, the embodiment of an optimal settlement pattern is impossibly complex and national urban policies should be formulated only with great care. Moreover, there are more direct and more effective methods to improve the quality of the urban environment than city-size adjustment strategies. The latter work very slowly, if at all, and are very difficult to implement. In any event, a by-product of such a strategy would be to deprive society of substantial economic, social and cultural benefits.

2. The wide scope of this paper inevitably means generalization, and this masks international differences. For instance, migration in developed countries increasingly means interurban movement, while in developing countries, rural-urban flows remain predominant. The settlement pattern develops differently according to whether changes are brought about by shifts between city-size classes or by over-all expansion in the urban population. In developed countries, regardless of the social costs and benefits, the private benefits of in-migration into large cities invariably exceed the private costs. In developing countries, this conclusion is less clear because of the possibility of rural expulsion.<sup>1</sup>

3. Apart from the discussion of primacy (see paras. 34-36), most of the empirical evidence quoted refers to

developed countries. In part, this reflects the severe data limitations in developing countries. Nevertheless, on *prima facie* grounds, the large cities of developing countries are more likely to generate net social benefits. If the later arguments on primacy are accepted, the social benefits of large cities in relation to small cities are probably stronger in developing than in the developed countries. Conversely, to the extent that social costs are a function of industrialization and affluence, they are weaker in developing countries. With a few conspicuous exceptions, there is reason to believe that the hypothetical critical city size that equates marginal costs and benefits is greater in developing countries.

4. The paper falls into two main parts. The first part focuses on the problem of the costs and benefits of city size, particularly at the upper end of the urban scale. An outline of the theoretical framework is followed by a discussion of negative, then positive, externalities. Lastly, some other considerations relevant to city size are briefly analysed: primacy; the market performance of city-size classes; and whether density is a more critical variable than city size. The second part broadens out the problem to that of the national settlement pattern as a whole and raises the questions whether there is an optimal spatial distribution and what the implications are for population distribution policy of growth, equity and environmental goals.

## OPTIMAL CITY SIZE

### Theory

5. The notion of an optimal settlement pattern depends heavily, though not inevitably, upon the concept of optimal city size. The latter has received a great deal of attention, primarily as a theoretical concept, but also, and more dangerously, as a guideline for policy prescriptions. The standard approach is to draw up sets of hypothetical cost and benefit curves (average and marginal) on a diagram in which city size (population) is measured on the horizontal axis. After an initial decline, the average costs (AC) function is usually drawn as rising more steeply than the average benefits (AB) function.<sup>2</sup> Several relevant sizes, frequently interpreted as optima, can be identified:

<sup>1</sup> On the other hand, it would be pointless to control city sizes without attacking the forces inducing the in-migration by such measures as land-tenure reform.

<sup>2</sup> In particular, a common assumption is that  $C' [P] > 0$  and  $C'' [P] > 0$  while  $B' [P] > 0$  and  $B'' [P] < 0$ . See also A. J. Brown, *The Framework of Regional Economics in the United Kingdom* (London, Cambridge University Press, 1972);

(Continued on next page)

- (a) *Minimum threshold*:  $AB = AC$ ,  
 where  $AB$  is rising and  $AC$  falling;  
 (b) *Least cost city size*:  $\text{Min } AC$ ;  
 (c) *Maximum resident welfare*:  $\text{Max } (AB - AC)$ ;  
 (d) *Maximum resident welfare under competition*:  
 $\text{Max } \beta (AB - AC)$ ,

where  $\beta$  = a parameter representing the proportion of net benefits remaining with the individual. This modification of (c) reflects the possibility that competitive demand for urban space in a situation where the supply of urban land is imperfectly elastic will result in part of the net benefits being swallowed up in higher land rents.<sup>3</sup> The value of  $\beta$  varies according to demand and supply conditions;

- (e) *Maximum gross benefits*:  $\text{Max } AB$ ;  
 (f) *Social optimum with unlimited population*:  
 $MB = MC$ ,

where  $MB$  = marginal benefits and  $MC$  = marginal costs. There is no reason why this should be achieved by market forces if the potential migrant makes his decision on the basis of  $AC$  and  $AB$ ;

- (g) *Social optimum with finite population*:  $MB - OC = MC$ ,

where  $OC$  = opportunity costs of locating the population elsewhere in the system.

6. Even this long list does not exhaust the possibilities, since the optimal city size may be viewed from the perspective of firms as well as households, and firms face a quite different set of cost and benefit functions.

7. To play this optimal city-size game involves several restrictive assumptions: the expression of city size in terms of urban area population; the additivity of all benefits and costs; the neglect of spatial variables in urban efficiency; the identity of interests of all citizens; homogeneity in tastes; and a static framework abstracting from shifts in production functions and from changes in household preferences. Of these, the second assumption is the most critical. Since the cost and benefit functions must, if they mean anything at all, take account of non-monetary costs and benefits (i.e., the social costs, such as pollution, congestion, mental stress and the risks of crime; and the social benefits, such as consumption externalities and business agglomeration economies), the shape of the functions can be known only if these costs and benefits can be specified. Since they cannot be measured precisely in monetary terms, any inference that cities of a certain size are

“excessive” or “too small” depends not upon scientific sifting of the evidence, but upon value judgements, implicit but untestable weighting assumptions and upon the criteria selected for analysis. For example, Klaassen<sup>4</sup> based his conclusions on the shape of the functions on a narrow definition of both benefits (incomes *per capita*) and costs (operating costs). Others have argued for an even smaller optimal size by giving excessive attention to the negative, but ignoring the positive externalities.

8. Thus, even if the optimal city size concept has some pedagogical value in a theoretical analysis, it is utterly non-operational for policy purposes. It has other objections. The distribution of costs and benefits may raise more critical issues for urban policy than their absolute magnitude.<sup>5</sup> The appropriate size for a city cannot be treated in isolation from its location in relation to other cities. Indeed, in a polynucleated megalopolitan structure the distinction between large cities and small becomes blurred, because small cities are frequently part of the large ones. The existence of national urban hierarchies dilutes the idea of a unique optimal city size into the much weaker proposition that there may be an optimum size for a city at a specific location at a particular point of time and in certain precisely specified conditions. This leads to the possibility of a great many optima, a result which does little to simplify the policy-maker's task.<sup>6</sup> In any event, city size is too ambiguous a term to be treated as a critical policy variable in social planning.

#### *Negative externalities and city size*

##### *A congestion and externalities model*

9. The standard model of externalities (particularly negative externalities) and city size derives from Tolley.<sup>7</sup> If it is assumed that there are increasing negative externalities with city size, the vertical difference between marginal private product (MPP) and marginal social product (MSP) widens as employment (population) expands. Furthermore, the MPP curve falls off more steeply. Market forces equate MPPs in cities. In a big city, equilibrium will occur at a larger population size than if MSPs had been equalized.<sup>8</sup>

10. There are two basic strategies to correct this situation. First, a policy of wage taxes and subsidies may be introduced to equalize wages and MSPs. This improves resource allocation and, within the assump-

<sup>5</sup> R. Kirwan, “The contribution of public expenditure and finance to the problems of inner London”, Centre for Environmental Studies Conference on the Inner City, Oxford, 1972; see also M. Edel, *loc. cit.*

<sup>6</sup> For an extensive treatment of the many weaknesses of optimal city-size analysis, see H. W. Richardson, “Optimality in city size, systems of cities and urban policy: a sceptic's view”, *Urban Studies*, vol. 9 (1972), pp. 29-48.

<sup>7</sup> G. S. Tolley, “The welfare economics of city bigness”, University of Chicago, Urban Economics Report No. 31, 1969.

<sup>8</sup> Tolley ignores positive externalities. If there are net positive externalities, market equilibrium can result in big cities being too small rather than too big.

tions of the model, reduces the size of large cities. However, as a solution it is second-best, since it leaves the negative externalities intact. A more efficient strategy is to take action to eliminate them by prohibition, taxes or subsidizing investment in abatement. The impact of such steps on the size of large cities is obscure. They could lead to a greater upward shift in the MP curves for large cities because of the assumption that externalities are greater there. For example, although pollution and congestion charges raise costs, the higher costs may be more than offset by shifts in production functions.

11. The value of this model, particularly as a precise guide for policy, depends upon the crucial assumption that negative externalities increase with city size. One may ask how firm the evidence is for the common assumption that social costs are an increasing function of city size and/or density.<sup>9</sup> It may also be asked how operational such a model is in view of the impossibility of measuring marginal social costs<sup>10</sup> and how one deals with the undeniable existence of offsetting agglomeration economies.<sup>11</sup> Whatever the difficulties of using this kind of framework for policy purposes, of the various control strategies—taxes, decrees, investment in new capacity or in abatement, and direct adjustment of city size—the last is dangerous and probably ineffective. Urban size is notoriously “sticky” downwards. There are no efficient instruments available to reduce city size sufficiently to have much impact on social costs. An advantage of congestion levies is that they are easily reversible and give scope for experiment denied to city-size adjustment strategies.

#### Traffic congestion

12. The rising social costs–city-size function is

<sup>9</sup>K. W. Kapp, *The Social Costs of Business Enterprise* (Bombay, Asia Publishing House, 1963); E. S. Mills and D. M. de Ferranti, “Market choices and optimum city size”, *American Economic Review*, vol. 61 (1971), pp. 340-345; K. W. Kapp, “Environmental disruption and social costs: a challenge to economics”, *Kyklos* (Bern), vol. 23 (1970), pp. 833-848; and J. Rothenberg, “Economics of congestion and pollution: an integrated view”, *American Economic Review*, vol. 60 (1970), pp. 114-121.

<sup>10</sup>See the objections raised by J. M. Buchanan, *Costs and Choice: An Inquiry in Economic Theory* (Chicago, Ill., Markham, 1969). Baumol and Oates make a convincing case for the use of charges to achieve predetermined environmental standards, rather than to attempt to equate social and private costs. Furthermore, the value of congestion itself as a rationing device should not be forgotten. See W. J. Baumol and W. E. Oates, “The use of standards and prices for protection of the environment”, in P. Bohm and A. V. Kneese, eds., *The Economics of Environment* (New York, Macmillan, 1971), pp. 53-65. For discussion of the question that a time tax is more equitable than a money tax, see E. Smolensky, N. Tideman and D. Nichols, “The economical uses of congestion”, *Papers and Proceedings, Regional Science Association*, vol. 26 (1971), pp. 37-52; and M. Johnson, “On the economics of road congestion”, *Econometrica*, vol. 32 (1964), pp. 137-150.

<sup>11</sup>Lave argues that congestion, pollution and other negative externalities should be taxed; but, simultaneously, if there are positive externalities, in-migration should be subsidized to maximize agglomeration economies. See L. B. Lave, “Congestion and urban location”, *Papers and Proceedings, Regional Science Association*, vol. 25 (1970), pp. 133-149.

plausible in respect of traffic congestion.<sup>12</sup> Congestion is an inverse function of speed, speed is inversely related to total vehicular flow (for a given road width) and flow is a direct function of city size; hence, congestion is positively associated with city size. Empirically, travel-time involved in work-trips increases with city size.<sup>13</sup> Similarly, peak central business district traffic densities are significantly higher in cities with more than 250,000 population than in smaller urban areas.

13. However, this evidence needs qualification in several respects. In cities above the 1 million mark, there may be some decline in traffic densities as mass transit systems become viable. Even if firms have no alternative to bearing higher freight and distribution costs apart from moving out of the city, households have much greater freedom for manoeuvre in the face of higher traffic congestion costs, by changing homes, jobs or transport modes. Congestion costs rise rapidly as road use (demand) increases in relation to design capacity (supply). Thus, if congestion costs are higher in larger cities the reason may be not so much ineradicable social costs or incorrect pricing of transportation services as chronic under-investment in transportation capacity. Unfortunately, remedying this situation may give rise to its own problems. In some of the world's largest cities, e.g., London, plans to expand the road transport system have met adverse public reaction because of environmental side-effects, particularly disturbance to residential-area amenity.<sup>14</sup>

#### Air pollution

14. The problems of urban pollution may be illustrated by the example of air pollution. The generation of air pollutants is an increasing function of population size and density, and of industrial concentration. Their effects on the quality of air are cumulative and complex, depending upon the volume and kind of pollutants emitted, their rate of dispersion and on chemical and physical reactions in the air. The relationship between pollution and city size, however, is obscure. What counts is the concentration of pollutants, and this is much more a function of density of population, vehicle use, industry etc. than of city size. Consequently, there are wide local variations even within a very small geographical area.<sup>15</sup>

<sup>12</sup>Congestion is understood here as the marginal social costs of travel, rather than in terms of physical flows.

<sup>13</sup>See J. N. Morgan, I. A. Sirageldin and N. Berwaldt, *Productive Americans*. Survey Research Center, Monograph 43 (Ann Arbor, University of Michigan, 1966); and A. M. Voorhees and others, “Factors in work-trip lengths”, *Highway Research Record*, No. 141 (1966), pp. 24-26. Even with a moderate valuation of travel-time the travel cost differential between adjacent city-size classes has been estimated at about 1 per cent. See I. Hoch, “Income and city size”, *Urban Studies*, vol. 9 (1972), pp. 299-328.

<sup>14</sup>For example, see United Kingdom, Department of the Environment, *Greater London Development Plan, Report of the Panel of Inquiry* (Her Majesty's Stationery Office, 1973), vol. 1, chaps. VIII-XV.

<sup>15</sup>For the very large variations in air pollution within Greater London, see Warren Spring Laboratory, *National Survey of Air Pollution, 1961-71* (London, Her Majesty's Stationery Office, 1972).

Climate and industrial structure are more important than city size; hence, regional variations in air pollution are much wider than intercity variations.<sup>16</sup> The differences between urban and rural areas are also very wide, compared with city-size class differentials, which fail to show a clear positive relationship. Seasonal variations within a city tend to be greater than the annual average differentials between cities. The association between air pollution and population density is stronger than that with either central city or urbanized area population.<sup>17</sup>

15. Paradoxically, in the developed countries, increasing concern with air-pollution problems has coincided with a significant decline in emissions over time. Not that this fact infringes the case for controlling air pollution. Lave and Seskin<sup>18</sup> have argued from evidence in the United States of America that a 50 per cent reduction in air pollution could lower the economic costs or morbidity and mortality by 4.5 per cent and increase the life expectancy of a new-born child by 3-5 years.

16. The question may be asked concerning the implications of the empirical evidence on urban air-pollution characteristics for pollution control. First, it would be futile to tamper with city sizes as a means of dealing with air pollution since it would also be necessary to change radically and simultaneously the density and structure of urban areas. A second and preferable strategy to influence the spatial distribution would be to encourage the decentralization of high-pollutant industries. Another palliative, no more than that since it can only affect future patterns, is to take account of direct and indirect air-pollution costs in selecting sites for new production plants. To deal with prevailing pollution levels more immediate measures are needed. These include setting nationally determined environmental regulations<sup>19</sup> and market incentives, e.g., emission fees and subsidies for pollution-abatement investment.

#### *Psycho-social stress*

17. One may ask whether psychological stress, alienation, social disorganization and higher propensities to be mentally ill are among the disadvantages of city size. This is an important question, though one on which this paper can offer only a lay assessment. In any event, it is generally recognized that the propositions are hard to test, while the evidence is sparse and conflicting.<sup>20</sup> Since costs due to stress cannot be measured,

<sup>16</sup> For the United States of America, see United States Department of Health, Education and Welfare, *Air Quality Data* (annual) (Washington, D.C., Government Printing Office).

<sup>19</sup> These regulations may provide a spur to technological advances, e.g., motor-car engine-emission standards proposed for 1975 by the federal Government of the United States of America.

<sup>20</sup> For a general survey, see G. Carlestam and L. Levi,

they are frequently exaggerated and given an absolute, sacrosanct value.

18. Some observers have emphasized the favourable effects of family life in small towns.<sup>21</sup> Others have argued that small-town life can be as alienating as life in big cities.<sup>22</sup> Even if the big city is a source of stress, one may ask how this stress can be balanced against its attributes as the fount of civilization. A few analysts<sup>23</sup> have quoted evidence on locational preference surveys which, together with numerous Gallup polls in many countries, indicate a preference for living in small towns, but answers to hypothetical questions of this kind are notoriously unreliable. Much of the argument has revolved around the relative impact of high urban population densities and overcrowding; and Jacobs,<sup>24</sup> among others, has argued the need to make a firm distinction between overcrowding (persons per room) and high population densities (persons per acre). The evidence in both cases is unclear. A study of Honolulu found that population per acre was more closely related than overcrowding to social disorganization measures.<sup>25</sup> On the other hand, Winsborough discovered no relationship with gross population density in Chicago after correcting for other socio-economic variables, and Mitchell's study of Hong Kong revealed no association between density and measures of strain and stress.<sup>26</sup>

19. Direct studies of the connexion between overcrowding and psycho-social stress have been even more equivocal. Too many studies have been based on extrapolations to humans from laboratory experiments with animals.<sup>27</sup> Other research has suggested an inverse

relationship between friendliness and city size.<sup>28</sup> More seriously, some epidemiological studies have found that the incidence of schizophrenia, neuroses and personality disorders is much higher in big-city slums.<sup>29</sup> However, this finding is difficult to interpret. Diagnosis rates may be higher in large cities. Also, it is unclear whether the higher incidence is due to the nature of social life in large cities or to some "drift" theory, i.e., a tendency for people with personality disorders to drift downwards into the poor neighbourhoods of large urban areas.

20. Overcrowding, high densities, pollution and noise may generate unfavourable psychological reactions that fall short of disease-inducing stress. However, these reactions differ according to social class, emphasis of the problem in the mass media and between individuals.<sup>30</sup> To the extent that there is empirical evidence on these questions, most of the emphasis has been on urban and rural differentials rather than on variations by city size.

21. Much more research needs to be done in this field. Even accepting the flimsy evidence in favour of the psycho-stress hypothesis at its face value, a question arises concerning the way in which these costs are to be balanced against the social and cultural attractions, not to mention the economic benefits, of the metropolis. Psycho-social stress arguments do not provide a case for a smaller "desirable" size of settlement as a guideline for national urban policy.

### Crime

22. The association between increased urbanization and higher crime rates is well known, but the causal relationships are difficult to disentangle. Furthermore, crime statistics are very unreliable and hard to interpret. Nevertheless, in both the United States of America and the United Kingdom of Great Britain and Northern Ireland, for example, there is some evidence of a positive association between crime rates (serious crimes per 100,000 population) and city size. In the United

<sup>28</sup> D. A. Hamburg, "Crowding, stranger contact, and aggressive behaviour", in L. Levi, ed., *Society, Stress and Disease: The Psychosocial Environment and Psychosomatic Diseases* (London, Oxford University Press, 1971), pp. 209-218; P. G. For a contrary view, see M. Fried and P. Gleicher, "Some sources of residential satisfaction in an urban slum", in H. M. Proshansky, W. H. Ittelson and L. G. Rivlin, eds., *Environmental Psychology: Man and His Physical Setting* (New York, Holt Rinehart and Winston, 1970), pp. 334-335.

<sup>29</sup> B. P. Dohrenwend and B. S. Dohrenwend, "Psychiatric disorder in urban settings", in G. Caplan, ed., *American Handbook of Psychiatry*, vol. III (New York, Basic Books, 1972); H. Strotzka, "Town planning and mental health", in H. P. David, ed., *Population and Mental Health* (Berne and Stuttgart, Hans Huber, 1964).

<sup>30</sup> In a view of noise-pollution research, it was observed that only about 25 per cent of the variability in reported annoyance could be explained by changes in noise levels. See P. N. Borsky, "Theoretical framework of factors influencing human annoyance and complaint reactions to environmental noise", paper prepared for the Fourth Karolinska Institute Symposium on Environmental Health, Stockholm, 1971.

Kingdom, crime rates are fairly similar in cities of over 200,000 population, though much lower in smaller towns.<sup>31</sup> In the United States, the decline in crime rates with decreasing city size is more regular,<sup>32</sup> though there is little difference between Standard Metropolitan Statistical Areas within the range of from 750,000 to 3 million.

23. Other aspects of the spatial incidence of crime in the United States obscure the city-size effect. The incidence of crime is much lower in rural than in urban areas, only about one third of the national average for serious crime. Within cities, the differential between central city and suburban crime is much wider than the interurban differentials, although suburban crime is becoming more prevalent. Within the central city, the heaviest concentration of crime is found in slum areas and in neighbourhoods troubled by social disorganization, i.e., in the ghettos. However, it is difficult to separate the racial effect from the city-size effect.<sup>33</sup> The higher economic costs of crime bear most heavily on the white high-income groups, but the poor (in the United States, especially the blacks) suffer most from the social costs.

24. The links between crime and population density are very complex. A few crimes (rape, assault, burglary) are lower in dense areas; and, some spread-out cities (e.g., Los Angeles) have very high crime rates.

25. Little doubt exists that there is a correlation between city size and crime, but the association is not very impressive. Certainly, as with the other social costs, there is no case for Utopian social engineers to prescribe physical planning or urban size-policy solutions to the crime problem.

### Positive externalities

#### Agglomeration economies

26. Although much of the emphasis in the city-size literature is on social costs, the social benefits of city size should not be neglected, in spite of the fact that their impact is, if anything, more difficult to measure. Urban agglomeration economies include: higher incomes; scale economies in the public sector (probably exhausted at a relatively small city size); a stable, diversified and highly productive economic structure; consumption externalities; and communication economies. A useful distinction may be drawn between business, household and social agglomeration economies.<sup>34</sup>

<sup>31</sup> See F. H. McClintock and N. H. Avison, *Crime in England and Wales* (London, Heinemann, 1968). It is not possible to examine city-size differentials for very recent years because of large-scale amalgamation of police forces.

<sup>32</sup> United States of America, Federal Bureau of Investigation, *Uniform Crime Reports for the United States* (annual) (Washington, D.C.).

<sup>33</sup> The black ghetto resident is perhaps 100 times more likely to be a crime victim than is the white suburban resident.

<sup>34</sup> H. W. Richardson, *Regional Growth Theory* (London, Macmillan, 1973).

27. Business agglomeration economies refer to the wide range of externalities associated with large cities that accrue to individual firms. They include: access to specialized business services; sources of capital; labour market economies (more varied skills, greater elasticity of labour supplies, superior training, better organized placement services); a larger stock of managerial and professional talent; the presence of facilities, e.g., good public services, a pleasant environment, cultural amenities likely to attract professional and high socio-economic status groups; opportunities for specialization offered by a large market (product specialization, technical externalities, transport cost savings); economies in water-supply and perhaps in other public services; information and communication economies (especially for face-to-face contact); greater adaptability and flexibility in the use of fixed capital (particularly structures); and the presence of business entertainment facilities.

28. Among household agglomeration economies, mention should be made of the opportunities for earning higher incomes, a wider choice of jobs, shopping facilities, quality of public services, leisure and cultural amenities and variety in housing. There are undoubtedly threshold city sizes in the efficient provision of educational facilities, public transportation, hospitals, leisure and entertainment opportunities, and in other types of social infrastructure; but there may be a levelling-off in many benefits at the medium-size range. Moreover, some amenities (e.g., climate, access to recreational areas of natural beauty) bear no relationship to city size.

29. Social agglomeration economies are more nebulous, though possibly more important. These economies refer to the systematic functions of large cities and their contribution to national economic growth. Foremost among these functions are the incubation of new industries and their subsequent "filtering-down"<sup>35</sup> to smaller cities and the role of large cities as centres of innovation and as the initial source of hierarchical diffusion.<sup>36</sup>

30. Although these paragraphs provide little more than a list of the positive externalities of urban scale, the length of the list is in itself a reflection that these benefits need as much analysis as the more newsworthy social costs. Unfortunately, there have been very few concrete conclusions on how these economies should be measured and on their precise variation with city size. However, from the systemic externalities point of

view, there are clear-cut policy implications: caution in any attempts to control the size of the country's largest cities; and intervention to boost the size of the dominant urban centres of backward regions in order to raise their rank in the national urban hierarchy.<sup>37</sup>

#### *Income and welfare*

31. The income data in developed countries indicate that both money incomes and the cost of living increase with city size,<sup>38</sup> but that the income variations are wider so that real incomes increase with city size. This is an important prop in the argument that big-city living confers private benefits. On the other hand, some analysts<sup>39</sup> have argued that the persistence of city-size income differentials despite convergence over time supports the "compensating payments hypothesis" (i.e., that workers in large cities have to be paid higher wages to compensate them for negative externalities). However, an alternative explanation is the effects of intermittent shifts in production functions.

32. *A priori*, urban growth might be expected to be associated with income inequality because of the regressive effects of rising population and the demand for land on urban rents. In fact, there is little evidence for a link between urbanization and poverty. In the United States, the incidence of poverty is two and a half times greater in non-metropolitan than in metropolitan areas, while within cities it declines steeply with increasing city size.<sup>40</sup> Relevant data are much scarcer in other countries, but casual empiricism suggests the same pattern. The myth of big-city poverty is probably explained by the large numbers of poor living in large cities and their heavy spatial concentration. A plausible explanation of the correspondence between income equality and city size is Kuznets' hypothesis that income equality is

<sup>37</sup> The justification is that this may promote both long-run efficiency and interregional equity.

<sup>38</sup> For the United States of America, see G. M. Neutze, *Economic Policy and the Size of Cities* (Canberra, Australian National University Press, 1965); V. R. Fuchs, *Differentials in Hourly Earnings by Region and City Size, 1959*, Occasional paper 101 (New York, National Bureau of Economic Research, 1967); K. Mera, "On the urban agglomeration and economic efficiency", *Economic Development and Cultural Change*, vol. 21 (1973), pp. 309-324; J. C. Brackett and H. H. Lamale, "Area differences in living costs", *American Statistical Association, Proceedings of Social Statistics Section*, 1967, pp. 144-148; E. Ruiz, "Urban family budgets updated to autumn 1971", *Monthly Labor Review*, June 1972, pp. 46-50; W. Alonso and M. Frajans, *Cost of Living and Income by Urban Size*, working paper No. 28 (Berkeley, Institute of Urban and Regional Development, University of California, 1970); D. Shefer, "Comparable living costs and urban size: a statistical analysis", *Journal of the American Institute of Planners*, vol. 36 (1970), pp. 417-421; I. Hoch, *loc. cit.*

<sup>39</sup> The dynamics of cost-of-living changes have been little explored. One study of 56 cities in the United States of America showed that prices tend to rise faster with increasing city size. See R. C. Bahr, M. R. Meiners and T. Nakayama, "New consumer price indices by size of city", *Monthly Labor Review*, August 1972, pp. 3-8; I. Hoch, *loc. cit.*; M. Edel, *loc. cit.*

Pedersen, "Innovation diffusion within and between national urban systems", *Geographical Analysis*, vol. 2 (1970), pp. 203-254.

functionally related to the average income level; this hypothesis was supported in a test of 207 Standard Metropolitan Statistical Areas.<sup>41</sup>

33. A disadvantage offsetting these income benefits may be a tendency for unemployment to be higher in large cities, especially for males.<sup>42</sup> It is also a common occurrence to find high unemployment rates in rapidly growing cities, i.e., a positive association between unemployment and net in-migration.

#### *Primacy*

34. Primacy occurs when the largest city in the urban system accounts for a much higher proportion of the total urban population than would be predicted from applying the more regular (rank-size, Pareto or lognormal) distribution formulae. Precise criteria and cut-off points are arbitrary. However, whatever definitions are used, many Latin American countries exhibit primacy, as do several Asian and a few European countries. In developing countries, primacy is frequently a pejorative term. However, it is more sensible to regard primacy as a symptom of problems of population distribution, e.g., the failure of agriculture to support rapidly growing populations and the absence of intermediate-size manufacturing and service cities, rather than as a cause. Whatever the diseconomies of urban scale in developing countries, they may be less unpleasant than the alternatives. To attempt to check the growth of large cities while neglecting the problems that induce their rapid growth may make matters worse.

35. The connexion between primacy and level of development is not clear-cut,<sup>43</sup> though few countries where primacy occurs are mature industrial economies. El Shaks argued that primacy is rare in the least developed of the developing countries, rises during rapid industrialization and declines thereafter; this is an urban-system equivalent of Friedmann's centre-periphery model of regional development.<sup>44</sup> Evidence has been found of positive association between primacy and population growth, export dependence and ex-colonial

status and a negative association with size, *per capita* income and industrialization.<sup>45</sup>

36. The equating of primacy with parasitism owes more to value judgements than to fact.<sup>46</sup> Indeed, in most cases, primacy has economic advantages: a higher social return to investment than at alternative locations; transportation advantages; economies of concentrating urban services in a capital-poor economy; the primate city has a key role as a source of innovation and managerial expertise and as a diffusion centre for modern attitudes as well as technical advances.<sup>47</sup> A recent study of 46 developing countries reveals quite a strong positive relationship between the economy's aggregate growth rate and increasing primacy.<sup>48</sup> All this suggests that in most developing countries, it is difficult to justify, on economic efficiency grounds, a population-distribution policy that discriminates against large cities. If such a policy were to be implemented, other objectives, such as interregional equity, would have to provide the justification.

#### *The market test of city size*

37. Presumably, households and firms have moved to (or stayed in) large cities because it was beneficial and profitable for them to do so. The question may be asked if one can, therefore, use the outcome of market forces as a test for the attractiveness of different city sizes. Such a hypothesis would require assuming no bars to mobility and competition between city-size classes for people and jobs. If, in the limiting case, one could assume no external economies or diseconomies; and, given the high correlation between the net movement of households and firms, it would be reasonable to argue that the size class which increases its population fastest is the most efficient from the societal point of view. The counter-arguments to this analysis are that the assumption of no externality is invalid and that even if large cities conferred net benefits in the past this may no longer be true today. In the latter case, locational inertia and the "locked-in" phenomenon may prevent a readjustment in city size in the absence of intervention.

38. One may ask how large cities fare in the market

<sup>41</sup> For the Kuznets' hypothesis, see S. Kuznets, "Economic growth and income inequality", *American Economic Review*, vol. 45 (1955), pp. 15-19. For the test of the hypothesis, see H. E. French III and L. S. Burns, "Metropolitan interpersonal income inequality: a comment", *Land Economics*, vol. 47 (1971), pp. 104-106.

<sup>47</sup> F. Herrera, "Nationalism and urbanisation in Latin America", *Ekistics* (Athens), vol. 32 (1971), pp. 369-373. Herrera argues that the metropolises of the larger Latin American countries are still not big enough. A size of from 5 million to 6 million may be appropriate to create the conditions needed to justify the development of intermediate manufacturing cities.

<sup>48</sup> K. Mera, *op. cit.*

test. Davis<sup>49</sup> showed that very large cities (over 8 million) grew more slowly than the others in the 1960s, but all the other size classes between 100,000 and 8 million increased at a similar rate. Alonso and Medrich<sup>50</sup> found in the United States that spontaneous growth centres (SGC) occurred throughout the size hierarchy. A frequently confirmed generalization is that growth rates for large cities are skewed to the right (either high or stable),<sup>51</sup> whereas smaller towns experience much wider deviations in their growth-performance, ranging from high positive to negative values.<sup>52</sup> Further, evidence in the United States for another indicator—increase in *per capita* income—shows that the big cities did as well as the small.<sup>53</sup>

39. On the whole, the large cities perform rather well. Nevertheless, it may be possible to salvage the pessimists' case. First, there may be unfavourable distributional effects in large cities (though the incidence of poverty is inversely related to city size). Secondly, in-migration may reinforce negative externalities, though not enough to force out existing residents. The trouble is that more research has been carried out on the negative than on the positive externalities. Also, many negative externalities are monetized (the "compensating payments" component in big-city incomes)<sup>54</sup> and though external to individual firms and households are internal to the urban economy as a whole. Thirdly, urban services and costs may be improperly priced, thereby encouraging excessive in-migration. In particular, migrants may pay only the average costs-per-unit increase in households, while the related marginal costs increase with city size. Although this argument may be valid, it involves several untested assumptions: that marginal costs do increase with city size; that the divergence from optimality could be eliminated by correct pricing; and that marginal social benefits are negligible or constant or decline with city size.

#### Density

40. In population distribution analysis and policy, population-density may be as relevant a variable as aggregate city size. For instance, there is some evidence that many external diseconomies (e.g., pollution, congestion) are a function of population density (especially central-city density) rather than of city size. Conversely, the provision of public services and certain types of

social infrastructure is costly at very low densities.<sup>55</sup> This suggests the possibility of a U-shaped function relating urban costs to population density. Some analysts<sup>56</sup> have argued that the concept of optimal density has some value. However, it is difficult to know what to make of such a concept since densities vary so widely within as well as between cities.<sup>57</sup> Just as the frequency distribution of cities casts considerable doubt on the validity of an optimal city size, so the spatial distribution of urban population densities throws suspicion on the usefulness of the "optimal density concept".<sup>58</sup> Although there are wide differences in central-city densities (and average densities) between developed and developing countries,<sup>59</sup> it is probably the intra-urban differences which have the most significant welfare effects. If high central densities imply heavy social costs, while low suburban densities confer higher levels of individual welfare (more space, cleaner air, easier access to open space), the wide income differentials between central city and suburbs are reinforced by density externalities. The solution to this intra-urban problem cannot be found in city-size adjustment strategies; but requires intra-metropolitan measures, e.g., extensive fiscal redistribution.

#### THE SETTLEMENT PATTERN

##### *An optimal spatial distribution*

41. The finding that the notion of a unique optimal city size is absurd is encouraging for city-size distribution analysis, since these distributions are, broadly speaking, hierarchical, indicating variability in size and a degree of regularity in the relationship between size-classes. It may be asked whether there is an optimal city-size distribution or an optimal spatial distribution of cities. Furthermore, accepting the importance of rural populations in some countries, it may be asked whether there is an optimal spatial settlement pattern.

42. Leaving aside the rural population question, a common method of expressing the urban population is in terms of a statistical distribution function. Of the alternatives, one of the simplest expressions is a rank size distribution,  $R = kP^{-q}$ , where  $R$  = city rank,  $P$  = city size and  $k$  and  $q$  = parametric constants. The value of  $q$  throws some light on the structure of the urban system:  $q = 1$  indicates the famous rank-size rule;<sup>60</sup>

<sup>49</sup> K. Davis, *World Urbanization, 1950-1970*, vol. 2 (Berkeley, Calif., University of California Press, 1972).

<sup>50</sup> Spontaneous growth centres were defined as urban centres with net in-migration rates of more than twice the national average. See W. Alonso and E. Medrich, "Spontaneous growth centers in twentieth century urbanization", in N. M. Hansen, ed., *Growth Centers in Regional Economic Development* (New York, Free Press, 1972), pp. 229-264.

<sup>51</sup> This phenomenon has been described as the "growth stability hypothesis". See W. R. Thompson, "Urban economic growth and development in a national system of cities", *loc. cit.*

<sup>52</sup> In part, this wider dispersion is to be expected merely on statistical grounds.

<sup>53</sup> "Metropolitan area income in 1970". *Survey of Current Business*, vol. 52, No. 5 (1972), pp. 27-44.

<sup>54</sup> I. Hoch, *loc. cit.*; G. S. Tolley, *loc. cit.*

<sup>56</sup> For example, W. F. Smith, *Housing: The Social and Economic Elements* (Berkeley, University of California Press, 1970).

<sup>57</sup> E. S. Mills, *Studies in the Structure of the Urban Economy, for Resources for the Future* (Baltimore, Md., Johns Hopkins Press, 1972); J. L. Barr, *Transportation Cost, Rent and Inter-urban Location* (St. Louis, Mo., Department of Economics of Washington University, 1970).

<sup>58</sup> H. W. Richardson, *The Economics of Urban Size* (Farnborough, United Kingdom, Saxon House, 1973).

<sup>59</sup> C. Clark, *Population Growth and Land Use* (New York, Macmillan, 1967).

<sup>60</sup> The rule states that the product of city size and its rank is a constant equal to the size of the leading city in the system.

$q > 1$  suggests metropolitan dominance, while  $q < 1$  points to an urban system in which there are large intermediate cities; and the limiting cases  $q = \infty$  and  $q = 0$  represent systems in which there is only one city and where all cities are the same size. Some analysts have argued that the rank-size rule represents the most probable outcome of a stochastic process.<sup>61</sup> Even if this were so, and it has been challenged, there is no reason why the most probable distribution should be optimal.<sup>62</sup>

43. In any event, city-size distribution parameters are too crude a measure of population distribution. They shed light only on relative, not absolute, size; the problem of "too many?" or "too few?" is different from that of "too big?" or "too small?" They ignore space, a fatal defect in the analysis of national settlement patterns. Clearly, a city of 150,000 which is in the suburbs of a giant metropolis is a quite different phenomenon from a central place of the same size in a rural region. It is possible to compute theoretical interurban distances,<sup>63</sup> but observed distances deviate widely from these. The finding that the size distribution is very stable over time may be more a reflection of the crudeness of how it is measured than an indication of immobility in the urban system. Lastly, ignoring the rural population is a limitation in many countries where the major functions of urban centres may be to service nearby rural areas.<sup>64</sup>

44. Unless attention is confined to a very abstract model (e.g., Lösch's assumption of a homogeneous plain over which resources are uniformly distributed), there is a wide range of alternative distributions of population in both spatial and size terms compatible with efficiency and social objectives. Even if a single dominant goal is assumed (e.g., efficiency, equity, environmental quality), it is impossible to determine the population distribution that best satisfies this goal. This question is discussed below. In any event, the capacity to alter the existing population distribution in order to make it conform to some preferred alternative is strictly limited. Furthermore, even if some population settlement-patterns are preferable to others, this is difficult to determine

<sup>61</sup> For an argument in support of the rank-size rule, see L. Curry, "The random spatial economy: an exploration in settlement theory", *Annals of the Association of American Geographers*, vol. 54 (1964), pp. 138-146. For a criticism of this approach, see P. Fano, "Organisation, city size distributions and central places", *Papers and Proceedings of the Regional Science Association*, vol. 22 (1969), pp. 29-38. Fano criticizes Curry's approach for neglecting systematic factors. Also, he suggests that a pure stochastic process would generate a different result, where each size class tends to have an equal number of cities.

<sup>62</sup> H. W. Richardson, "Optimality in city size, systems of cities and urban policy: a sceptic's view", *loc. cit.*

<sup>63</sup> See A. Lösch, *The Economics of Location* (New Haven, Conn., Yale University Press, 1954); L. Curry, "Central places in the random spatial economy", *Journal of Regional Science*, vol. 7 (1967), pp. 217-238; C. T. Stewart, Jr., "The size and spacing of cities", in H. Mayer and C. F. Kohn, eds., *Readings in Urban Geography* (Chicago, Ill., University of Chicago Press, 1959), pp. 240-256.

<sup>64</sup> It is interesting that the standard central-place hierarchy model is built upon a rural population base. See M. J. Beckmann, "City hierarchies and the distribution of city sizes", *Economic Development and Cultural Change*, vol. 6 (1958), pp. 243-248.

*a priori*. Much depends upon the irregularity and topographical features of the space economy in question, the distribution of natural resources, the past and current population distribution, the production technology (which determines economies of scale in industry and the structure of transport costs),<sup>65</sup> locational constants and random factors. Provided that policy objectives are broad in scope, it may be possible to identify an unsatisfactory settlement pattern and to improve it gradually. This is more realistic, as well as being more modest, than attempting to determine an optimal spatial distribution. In a dynamic context, and over heterogeneous space, such an optimal distribution is at best very complex, perhaps impossible.

#### *Population distribution policy and economic growth*

45. The population distribution that results from the operation of market forces is reasonably efficient in the narrow economic sense of promoting a high rate of growth in gross national product. Resource allocation may be improved by subsidizing positive and taxing negative externalities, and such intervention might bring about some realignment in the city-size distribution. However, apart from the fact that a taxation-subsidy strategy on these lines is currently unfeasible, it is unlikely that the over-all city-size distribution would look markedly different. The evidence suggests that private returns to labour and (probably) to capital are higher in large cities. As previously remarked, the primacy-growth rate link appears to be fairly strong, at least in developing countries. The national urban hierarchy, and a hierarchical city-size distribution, is the outcome of market forces, is an efficient form of population distribution and spatial organization for the achievement of growth goals. If growth goals justify a case for intervention, the case is most strongly based on the time-horizon over which gross national product is to be maximized. A very long time-horizon may justify action now to promote the growth of the major urban centres of backward regions in preference to the more concentrated and polarized pattern of development resulting from short-term market forces. In this case, intervention may be more efficient by redistributing population along a superior path of adjustment towards the more dispersed pattern of national settlement that would eventually develop in the market economy.

#### *Population distribution policy and equity goals*

46. If the economy is viewed in terms of continuous space rather than as divided into a set of arbitrary regions (each of which is assumed homogeneous and lacking spatial differentiation) the concept of spatial equity becomes very blurred. Equity problems may arise at the intra-urban, interurban (intra-regional) and interregional levels. One may ask whether urban size-

<sup>65</sup> The spatial distribution of population and economic activities reflects economies of scale (lower bounds) and transport costs (upper bounds) which stratify population into a hierarchy of cities and settlements and determine the number and size of urban places at each level.

policies can be used to pursue equity objectives. The answer is "not very easily". For instance, growth-centre strategies in backward regions certainly promote interregional equity, but may have adverse effects on intra-regional equity. Moreover, it is dubious whether attempts to check the growth of large cities are desirable from an equity point of view. As pointed out above, poverty indexes and measures of income distribution suggest the contrary. On the other hand, the absolute gap between the very rich and the more numerous very poor is probably wider in the large city. Furthermore, rapid urban growth may bring about changes in the relative price structure (e.g., higher land values) which may regressively shift the functional distribution of income. The ambiguities and contradictions involved in pursuit of equity goals in a spatial context indicate that such goals are far better tackled by redistributive fiscal and wage policies rather than by tampering with city sizes.

#### *Population distribution policy and environmental goals*

47. Environmental goals are assuming increasing importance among the social and economic policy objectives of most countries, whether developed or developing. However, it may be argued that the relationship between population distribution and environmental resources is more satisfactorily examined and dealt with at the aggregate level, in the sense that it is unclear whether alternative settlement patterns will have significant differential effects on the use of environmental resources. Of course, as already observed, the degree of population concentration may have effects on the urban environment and quality of life (e.g., air pollution, visual satisfaction derived from the built environment, noise and stress due to overcrowding). Even in these cases, however, it is arguable that attempts to alter the settlement pattern are inappropriate. Such action may be unfeasible in a given institutional environment or may work much too slowly. Technical solutions and/or institutional change are a more direct and more effective method of dealing with environmental externalities than physical planning or national urban policy prescriptions. To the extent that any spatial modifications are desirable, planned decentralization within a polynucleated metropolitan area is more feasible than diverting population to smaller, distant urban areas.

48. Some environmentalists argue that particular population settlement patterns minimize the strain on environmental resources. Apart from the self-evident fact that uniformly low densities of people and industries would reduce the adverse impacts of environmental disruption due to concentration, it is difficult to know what this means. In any event, this particular observation is irrelevant since its policy implication is unrealistic. Since spatial economies of scale exist, the benefits of concentration have to be evaluated along with the costs. More ambitious strategies, such as the redistribution of population into small, regularly dispersed settlements,<sup>66</sup> are idealistic, anachronistic and

<sup>66</sup> For an extreme suggestion of this kind see "A blueprint for survival", *Ecologist*, January 1972.

impractical. They would not reduce the claims on natural resources unless accompanied by radical, and as yet mainly undiscovered, changes in technology, many of which may be implemented without drastic changes in population distribution. Once environmentalists descend to specifics, policy prescriptions are often contradictory. A common example is the simultaneous recommendation to reduce city sizes and to control urban motor-car use (to reduce pollution and congestion, slow down the building of urban motorways and reduce petroleum demand).<sup>67</sup> The limitation of private vehicle use in cities requires switching to an efficient public transport system, which is viable only in large cities. On current evidence, the problem of environmental conservation<sup>68</sup> is more appropriately tackled by (possibly drastic) social, technical and economic policies affecting society as a whole, rather than by modifications in the population settlement pattern.

#### *The uneasy case for a population distribution policy*

49. The argument of this paper is not that no scope exists for a national urban policy. Particularly in countries where population is growing rapidly and/or where the national urban hierarchy is imperfectly formed, such as in many developing countries, policy-makers may have considerable leverage on the settlement pattern. Housing policies, social infrastructure investments and physical planning decisions have to be made in any event; and to the extent that people's needs have to be anticipated and their locational behaviour is influenced by the provision of housing and social capital, it would be wrong not to locate urban capital at places and in amounts considered socially desirable. The capacity to mould the settlement pattern is much greater in these cases than in the mature, developed economy with a high degree of urbanization and a low projected rate of population growth. The implication of this argument is that the choice of an appropriate policy, or indeed whether a policy is necessary, cannot be divorced from the specifics of an individual country—its institutional environment, level of development, rate of growth, demographic characteristics, existing urban structure and other factors.

50. One distinction between urban-size strategies and aggregate population policy is that measures for the former concentrate, directly and indirectly, far more upon migration rates than on reducing fertility. If changes in the rate and direction of intranational migration flows are the primary form that city-size adjustment takes, then measures to check certain city sizes or to

<sup>67</sup> The encouragement of decentralization may give rise to similar contradictions.

<sup>68</sup> Another aspect of environmental conservation, a subject of much attention in such small densely populated developed countries as the United Kingdom, is the preservation of the countryside and ensuring access to open space. Pursuit of these objectives has implications for settlement policy, but the interactions are too complex to explore here. However, they raise problems for the spatial distribution of population much more than for the size distribution. To the extent that they affect the size distribution, dispersion into small rural settlements, if practical, could have severe adverse effects.

boost others have repercussions elsewhere in the economy. It is important, therefore, to recognize the interdependence of the interurban system and the feedbacks between the urban and rural economies. Despite the crucial importance of migration in differential urban growth, very few countries adopt migration subsidies and controls as instruments. The reasons are obvious, though not necessarily overwhelming. There are so many different types of migration streams that net flows are difficult to monitor and control. Direct migration controls on household movements are hard to sell politically, and evasion would be relatively easy. Migration subsidies are more practicable, but the level of subsidy may need to be high to counteract the pull of market forces towards particular cities. Furthermore, a side-effect may be to induce a higher over-all migration rate, whereas in many circumstances a reduction in this rate is required. Many policy-makers prefer to influence migration indirectly by subsidizing job creation at specific locations, capable of diverting migrants from their "preferred" destinations. This strategy assumes that employment opportunities are the main determinants of migration. A middle course occasionally suggested is to subsidize employers in fast-growing (but still suboptimal?) cities according to their capacity to absorb migrants, but lavish aid to prosperous cities is difficult to justify upon equity grounds.

51. Urban-size strategies have had a mixed success, and there have been very few co-ordinated attempts to influence the size distribution as a whole rather than acting on specific size ranges (e.g., controlling the largest metropolis, growth centre and new towns policies, agricultural marketing and service centre strategy). Too little is known about the effectiveness of various instruments. One may ask whether, if migration subsidies are impractical, investment incentives are more or less effective than infrastructure investment for attracting jobs. For the control of large cities, there is scope for both prohibitive controls (land-use controls, factory licences) and pricing policies (payroll taxes, pollution charges, congestion taxes). In developed countries, intra-urban controls are more powerful, and their effects more predictable, than interurban instruments. If this is so, the emphasis shifts away from size to structure, and polynucleated clusters of cities may be more satisfactory from efficiency, equity and social points of view than manipulating the size of "free-standing" cities. Since many national and regional policies (agricultural policy, fiscal measures, industrial strategy) have indirect effects on urban size, their influence should be taken into account. On the other hand, for many urban problems, pollution being a good example, technical solutions and pricing strategies are more effective than size-control measures. Environmental instruments may also be relevant to the promotion of smaller cities if amenities are considered an important locational attractor.<sup>69</sup>

<sup>69</sup> L. H. Klaassen, *Social Amenities in Area Economic Growth* (Paris, Organisation for Economic Co-operation and Development, 1968).

52. Apart from the bluntness and limited effectiveness of urban policy instruments, a more critical question is that of the scope for a national urban size (or, more generally, national settlement pattern) policy. The solutions to many so-called "urban" problems (crime, stress, poverty, race, drugs, even pollution and congestion) are not to be found by altering the national settlement pattern. These are problems "in" cities rather than "of" cities,<sup>70</sup> and national urban strategies cannot solve general economic and social problems. As suggested above, many goals may be relevant to a national population distribution policy,<sup>71</sup> but changing the distribution of city sizes is too clumsy and too broad a strategy for dealing with a set of multiple, and occasionally conflicting, goals. Certainly, there is no evidence to suggest that a more even size-distribution of cities implies either greater efficiency or higher welfare than a skewed distribution. The neat theoretical prescription of equating marginal social benefits and costs is non-operational because most of the social costs and benefits cannot be measured; and, hence, the appropriate taxes and subsidies cannot be determined, even if a marginal cost pricing strategy were politically acceptable.

53. One component of national urban policy that has received widespread application is a growth-centre strategy. The aim here is to boost the size of urban centres, particularly in lagging regions, to the level where growth becomes self-sustaining. However, growth-centre policies manifest themselves in different ways. The size of growth centres may vary widely according to whether the objective is to develop rural service centres, to articulate a polarized spatial strategy for regional development, or to promote counter-magnets to a major metropolis.<sup>72</sup> At one extreme, e.g., Sweden and Northern Canada, the lower size-limit may be 15,000-30,000; in many other countries, 250,000 is considered a minimum critical size.

54. The growth-centre approach can be treated only as one aspect of a population distribution policy. Its validity is based primarily upon its usefulness as a regional rather than a national spatial strategy. Growth-centre policies have had little impact upon the size-distribution of cities. This situation reflects in part the limited period in which policies have operated; and it is due in part to the fact that the more successful experience has been where resources have been concentrated on a very few centres, which show up as no

<sup>70</sup> W. Alonso, *Problems, Purposes and Implicit Policies for a National Strategy of Urbanization*, working paper No. 158 (Berkeley, Institute of Urban and Regional Development of the University of California, 1972); M. Webber, "The post-city age", *Daedalus*, vol. 97 (1968), pp. 1091-1110.

<sup>71</sup> In effect, only three goals have been explicitly considered in this paper (efficiency, equity, environmental quality). For a much longer list, see H. W. Richardson, "Optimality in city size, systems of cities and urban policy: a sceptic's view", *loc. cit.*

<sup>72</sup> See N. M. Hansen, ed., *Growth Centers in Regional Economic Development* (New York, Free Press, 1972); A. Kuklinski, ed., *Growth Poles and Growth Centres in Regional Planning* (The Hague, Mouton and Co., 1972); A. Kuklinski

(Continued on next page)

more than a minor kink on the rank-size curve. Lastly, the theoretical framework for growth-pole analysis (e.g., the links between propulsive industries, the dynamics of technical change and spatial externalities) has been devised and most of the practical applications have occurred in mixed developed economies. There is very little evidence that this type of strategy is suited for developing countries.

#### CONCLUSION

55. The foregoing discussion suggests that an optimal spatial distribution of population is elusive. The hierarchical structure of cities, and the metropolises at the apex of the hierarchy, are important for efficiency, welfare and for the attainment of regional and national objectives. There is little evidence that large cities, in any objective sense, are too large. If higher costs are outweighed by higher productivity, the problem is one of income distribution, not a diseconomy of scale. On the other hand, even if it is difficult to argue that a particular level of urban population is too high, there may be some circumstances in which city growth rates

are too rapid,<sup>73</sup> especially from the point of view of maintaining environmental quality standards. However, this is not a problem of city size *per se*, but of the absorption rate.

56. There is a strong case for pragmatism and for the pursuit of attainable goals using feasible instruments. Clearly, a city-size equalization strategy would be wrong. There is scope for measures to influence the national urban hierarchy, for instance, by promoting growth centres and perhaps by stimulating decentralization from the largest cities. On the other hand, it would be futile to try to redistribute population directly from the large cities to smaller distant urban centres in other regions. This strategy would dissipate resources that could be more sensibly deployed elsewhere. In particular, the dangers of grandiose national population distribution strategies are that they divert attention from the crucial tasks of remedying the most obvious resource misallocations within the city and of improving the quality of life where risks of deterioration are greatest. Urbanization is not undesirable, but it may improve welfare rather less than it boosts growth. Hence, the solution is not to check urbanization *per se*, but to correct for its side-effects.

<sup>73</sup> Rising marginal costs may reflect inelastic short-run supply functions rather than "real" higher social costs.

## SELF-HELP CITY: THE INTERNAL ORGANIZATION OF METROPOLITAN AREAS\*

Charles M. Correa\*\*

### THE PROBLEM AND THE OPPORTUNITY

1. Throughout the developing world, urban centres are growing. As recently as 1941, Bombay had a population of 1.5 million; today it has almost 6 million; within a decade it is expected to exceed 10 million.<sup>1</sup>

2. Furthermore, Bombay is not an isolated phenomenon.<sup>2</sup> Estimates vary; but in general over the next 25 years, the urban population of India is expected to grow from 100 million to at least 300 million. This is owing in part to the growth of the urban sector (from the current 18 per cent to an expected 30 per cent<sup>3</sup> of the population), and in part to an absolute growth of the population (from a current level of 560 million to just over 1,000 million in the year 2000).

3. There can be no doubt that, under this kind of pressure, cities will crack.<sup>4</sup> Calcutta is already the first casualty. After all, in many of these cities, there already exist considerable shortfalls in the service and social infrastructure, not to mention housing. By Government count, approximately 12 million new housing units must be built in the urban areas in order to meet existing needs.<sup>5</sup>

4. It is evident that growth on this scale necessitates several different strategies which must be implemented simultaneously:

(a) The first is to create growth centres at the village and small-town level;<sup>6</sup>

\* The original text of this paper (E/CONF.60/SYM.III/9) was submitted to the Symposium on Population, Resources and Environment, Stockholm, 26 September-5 October 1973.

\*\* City planner of "New Bombay", Bombay, India.

<sup>1</sup> Report of the Bombay Metropolitan Regional Planning Board, 1969.

<sup>2</sup> The urban/rural population of developing countries, 9 per cent (in 1940) and 15 per cent (in 1960), is estimated to reach 31 per cent (in 2000); see *Growth of the World's Urban and Rural Population 1920-2000*, Population Study No. 44 (United Nations publication, Sales No. E.69.XIII.3).

<sup>3</sup> In three major states—Gujarat, Bengal and Maharashtra, the urban sector is either near or over this figure. See *Report on Population Projections* (New Delhi, Government of India, Press, 1968).

<sup>4</sup> In India, the larger urban centres have a higher population growth than the smaller ones. See Rafiq Zakaria, *Augmentation of Financial Resources of Urban Local Bodies* (Delhi, Government of India Press).

<sup>5</sup> India, Ministry of Housing, *Report on Housing* (Delhi, Government of India Press, 1965).

<sup>6</sup> What John Lewis calls "town-centred" growth. See John Lewis, *Quiet Crisis in India* (Washington, D.C., The Brookings Institution, 1962).

(b) The second is to encourage the growth of new towns and cities in the less developed parts of the country, which will act as countermagnets to the large metropolitan centres of Bombay, Calcutta, Delhi and Madras;<sup>7</sup>

(c) Because both strategies (a) and (b) would have a take-off period of at least 10-15 years, there must simultaneously be strategies that allow the existing metropolitan centres to function during this take-off period.

5. If the first two strategies fail, there is a real possibility that a city like Bombay may reach a population of from 50 million to 60 million by the turn of the century (as some demographers have predicted).<sup>8</sup> But even if these strategies are successful, there still remains the problem of making Bombay function with as many as 10 million or 12 million people in it, and all this in the space of little more than a decade.

6. A number of cities throughout the world are growing at this rate. For instance, since 1950, the population of Abidjan (Ivory Coast) has grown from 69,000 to well over 500,000; Lagos (Nigeria), from under 250,000 to 1,500,000; Bangkok (Thailand), from less than 1 million to 3 million; and Bogota (Colombia), from 650,000 to over 2,500,000. In some of these cities, it may be possible to achieve this growth within the existing land-use and infrastructure pattern. However, it is the main purport of this paper that in the majority of cases, there might be considerable advantages—both in economic costs and social benefit—to develop new land-use patterns on a large scale, either within, or continuous to, the existing city.

7. Furthermore, if one can succeed in rationally coordinating responses to this urban-growth phenomenon,

<sup>7</sup> This dilemma between rural and urban priorities has led to increasing attention to the possibility of accelerating development of small- and medium-size towns or creating new urban growth centres. At least *prima facie*, such an approach appears to combine many advantages. It would relieve population pressures both in the major cities and the countryside, increase the modernization spin-off which urban centres provide to surrounding rural areas, provide less congested and polluted urban living at an infrastructure cost no greater and possibly less than in the main cities. It should also reduce regional imbalances and capture to a greater extent the potential initiative from regional decentralization". International Bank for Reconstruction and Development, "Urbanization". Sector working paper, June 1972.

<sup>8</sup> Roy Turner, ed., *India's Urban Future* (Berkeley, Calif., University of California Press, 1962).

then it might actually be possible to use this enormous quantum jump to permanent advantage, and to emerge from the tunnel, so to speak, better off than before it was entered. After all, most cities in the past have grown by continuous incremental stages. Thus, the authorities never perceived the opportunity to "re-arrange the scenery", as Buckminster Fuller puts it: for instance, turn the clock back to the time when New York City had only 1 million or 2 million inhabitants. If, at that stage, it had been apparent that the city would soon have to accommodate 10 million people, many basic structural changes might have been not only financially possible, but politically viable; and New York today would be a far more rationally organized city.

8. This approach has a further advantage: it is, perhaps, the only way one can urbanize within the almost implacable financial constraints prevailing in developing countries. For example, in the urban areas of India, the income per family is extremely low: 25 per cent earn less than Rs 200 per month; and the next 50 per cent between Rs 200 and Rs 500.<sup>9</sup> Even if one assumes a rent-paying capacity at 25 per cent of this income (high by Indian standards for this income level), then, using brick and concrete, very little can be constructed for this money—somewhere between 1.5 m<sup>2</sup> and 5 m<sup>2</sup> per family—and this for 75 per cent of the population. Of course, simple mud and bamboo houses built in self-help schemes are very much cheaper; but the cost of land anywhere near the city centre becomes exorbitant. Thus, these "sites-and-services" schemes tend to be located on the periphery of cities, not a very happy location as the inhabitants are far away from the main mass transport lines and have no job mobility. In fact, these schemes tend to become ghettos of unemployment at the mercy of one or two local employers. Putting in a mass transport system can be expensive, as is often the augmentation of the other existing municipal services.

9. On the other hand, there are the advocates of high-rise, high-density housing schemes, such as are found in Hong Kong and in Singapore. Here, the cost of service infrastructure is much lower and mass transport is cheaper. However, the cost of the housing unit itself is beyond the reach of the families in question and must be subsidized, but subsidy might have other priorities, such as health, education etc.

10. Thus, one sees that as long as the problem is being dealt with in small bits and pieces within an existing urban context, there doesn't appear to be any solution in sight. One must, of necessity, examine the entire system called "city" and try to arrive at a solution which is the most economical in its total cost per family, including roads, services, schools, mass transportation systems, green areas and, of course, the housing unit itself.

<sup>9</sup>Only 8 per cent of households earn more than Rs 1,000 per month. See P. Ramchandaran, *Housing Situation in Greater Bombay* (1972).

11. This strategy is, in fact, currently being implemented in "New Bombay", a growth centre for 2 million people across the harbour from the old city. It is an attempt to shift the office jobs (which, in Bombay, are growing three times as rapidly as industrial jobs) away from the old city, so that, in one stroke, the pressure on the existing city centre is relieved and a key input is added to the urban equation across the harbour. The state government has acquired 22,000 hectares of land (some scrub, some farming) and has set up a development corporation<sup>10</sup> to design and develop the new city. The enhanced value of the developed land will be used to finance the service and social infrastructure, mass transport and housing for the poor. This pattern of cash flow requires only minimal seed capital (in this case Rs 120 million). In such a venture and with such an opportunity, it may be asked how one goes about "arranging the scenery".

#### ARRANGING THE SCENERY

12. To answer the question concerning arranging the scenery, one must ask what the urban Indian expects from his city.

13. In an Indian city today, the first thing that strikes the visitor is the pervasive poverty. This urban poverty is perhaps the worst pollution of all. Long before one sees the smoke in the sky or smells the sulphur in the air, one sees the people living and dying on the pavements. One may ask whether it is inevitable that poverty should degrade life in this manner. The same poverty, in rural India, has a far different expression. The people are as poor, in fact, perhaps even poorer, but they are not dehumanized. In the village environment, there is always space to meet and talk, to cook, to wash clothes. There is always a place for the children to play. One need not take a look at how these same activities occur in Indian cities. Pollution is primarily caused by the misuse of the environment. Obviously, there is no relation between the way cities have been built and the way people use them.

14. Living in an Asian city involves much more than the use of a small room of, say, 10 or 20 m<sup>2</sup>. Life in a city necessitates a whole spectrum of activities; it calls for spaces ranging all the way from a place to wash clothes to large community areas for games, public meetings etc. Unless one provides this entire hierarchy of spaces, one has not provided for people.<sup>11</sup> Building

<sup>10</sup>The City and Industrial Development Corporation (CIDCO), a quasi governmental agency with statutory powers.

<sup>11</sup>In the Indian context, this might mean:

(a) A small terrace or courtyard, open to sky, usable as a private outdoor room. This space is crucial. It is a multi-purpose space usable for many activities, e.g., grinding the *masala*, hanging out clothes to dry, a space where the child can play under supervision—in other words, a multipurpose spill-over space;

(b) The doorstep and the pedestrian path. This is where one may gossip with one's neighbour, one's child can play marbles etc.;

(c) Larger group spaces. For instance, in Indian villages, the village well. It is really a space for talking and loitering:

(Continued on next page)

## HOUSING COSTS AND LAND-USE ALLOCATIONS

housing involves much more than building houses. The little tenement at the end of the line is only one in a complex system of a family's spatial requirements; and this is, perhaps, even truer of the developed countries where, owing to higher family incomes, these requirements become more space-intensive and sophisticated.<sup>12</sup> What is being observed today is the desperate efforts of people—especially the poor—to try and work out in some way a pattern of living within the totally inadequate context provided for them. But then the question arises whether funds are adequate and whether there is enough space in Indian cities to provide an adequate pattern of living.

15. In looking at land-use allocations in cities around the world, one observes, in most cases, that only from 30 per cent to 40 per cent of the area of a city is devoted to residential use. (The remainder is used for commerce, industry, transport, recreation etc.) Furthermore, if one examines these residential areas, one finds that only about half the land therein is devoted to the building plots themselves. For instance, for a city of 2 million, calculations show that while the area required for the over-all city is approximately 11,900 hectares, the area required for the building sites in the residential sectors<sup>13</sup> constitutes 1,600 hectares, i.e., about 14 per cent of the total land use.

16. Now, if one doubles the number of dwelling units per residential plot, one would reduce the space required for building sites from 1,600 hectares to 800 hectares, plus another 25 per cent reduction (200 hectares) for local distributory roads. One would not be saving more than 1,000 hectares—that is, about 8 per cent of the total area required by the city. If, on the other hand, one halves the available area on each residential plot, then the total area required by the city would increase by 2,000 hectares (by approximately 16 per cent). But one may ask—and this is the heart of the matter—whether these variations in the residential densities<sup>14</sup> make a crucial difference in the living patterns—really the life-styles—of the people in Indian cities. And, furthermore, it may be asked whether they also make a decisive difference in the cost of the dwelling units themselves.

(d) The main community space. This is the large area, the *maidan*: it is the space to kick a football, to fly a kite or to hear a political speech. It is common to the whole community.

<sup>12</sup> Peter Rich, *Notes on low-rise, high-density housing* (London, 1966).

<sup>13</sup> The gross residential densities (including building sites, distributory roads, schools, children's playgrounds, community facilities etc.) come to approximately 650 persons per hectare: a reasonably high density, easily achievable in a developing country, since the number of members per household (five) is larger and the carpet-area per household (20 m<sup>2</sup>) is considerably smaller than the levels prevailing in developed countries.

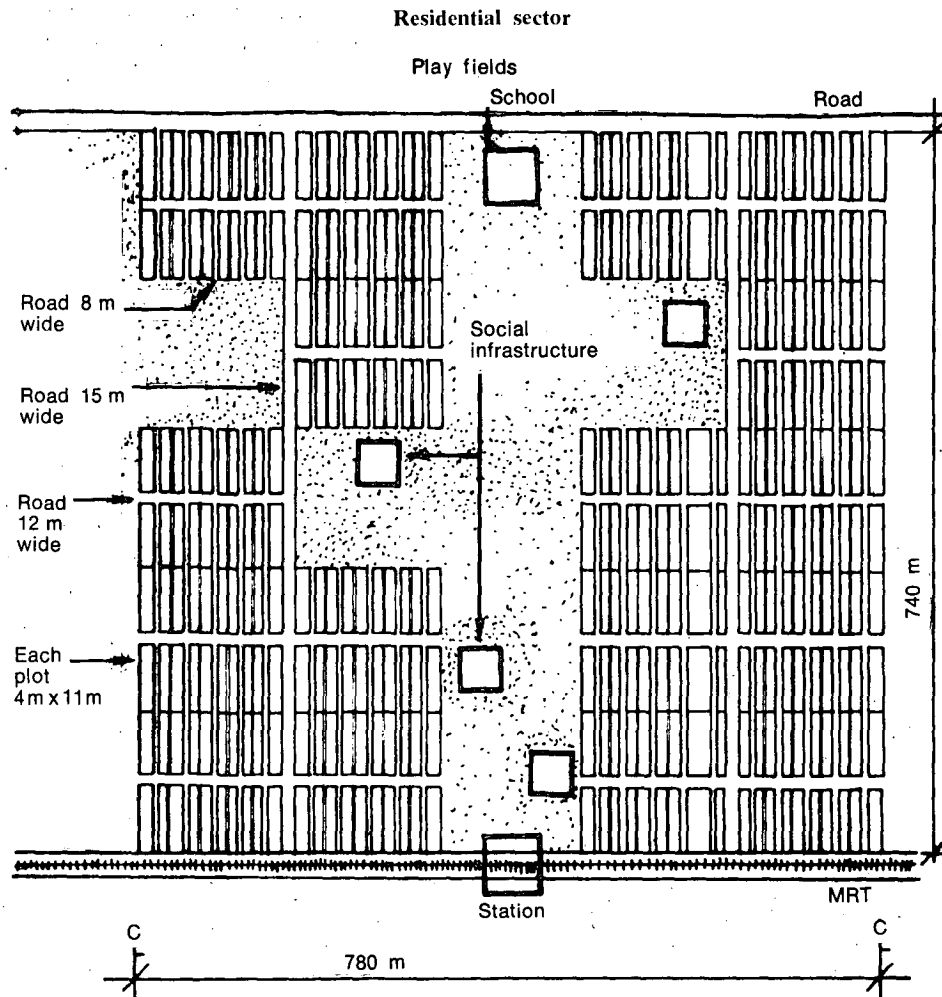

<sup>14</sup> Studies undertaken for Hook, a new town in the United Kingdom, show that, assuming a circular town, reducing residential densities from 250 persons per hectare to 100 persons per hectare would increase the area of the circle by 42 per cent, but the radius (i.e., distance from periphery to city centre) by only 19 per cent. See Greater London Council, *Planning a New Town* (London, 1965).

17. Obviously what one must do is attempt to identify those housing patterns and densities wherein costs and benefits are in optimal balance. To begin, three typical housing patterns are examined: (a) ground-floor terrace houses on small individual plots; (b) four-storey walk-ups; and (c) ten-storey high-rise buildings. The figure given below shows a residential sector, 780 by 740 metres. Everyone lives within from six to eight minutes walking distance of the mass-transit stop. The social infrastructure (at 30 m<sup>2</sup> per family, for kindergarten schools, children's playgrounds, local shopping, health centres etc.) is along the pedestrian green spine which runs down the middle of the sector. The land-extensive uses (such as playing fields) have been kept just outside the sector, farthest away from the mass transit so as to minimize service infrastructure costs.

18. Assuming an average carpet area of 32 m<sup>2</sup> per family, gross residential densities are achieved approximately as follows: 500 persons per hectare using ground-floor houses (on individual plots of 4 × 11 metres each); 750 persons per hectare using four-storey walk-ups; and 1,000 persons per hectare using buildings of 10 storeys. (Density is not a direct function of the height of the buildings. This is due in part to the fact that the taller the buildings, the further apart they must be; and in part to the social infrastructure area *per capita* being constant.)

19. The cost of the five-storey walk-up tenements is approximately Rs 14,200; the cost of service infrastructure (roads etc.) is Rs 1,600, i.e., about 12 per cent of the total cost. Increasing the density to 10 storey high-rise buildings will reduce the service infrastructure cost to Rs 1,100 per tenement; however, this saving is more than offset by the additional cost of elevators, fire-fighting provisions etc. (not to mention the maintenance cost and replacement cost of such sophisticated equipment, usually obtainable only at a premium in developing countries). On the other hand, reducing the density to ground-floor houses, though it increases the cost of service infrastructure to Rs 2,250 per unit, is actually no more expensive, since this extra cost is compensated by the fact that individual ground-floor houses do not require the circulation corridors etc. of walk-up tenements (circulation corridors consume about 12 per cent of the total built-up area). Furthermore, since a ground-floor house can be built in stages, one can begin with a single room, a water-closet and a water-tap in the courtyard. The roofless courtyard is really additional living-space of crucial value to the family, a benefit that must enter into one's calculations as a negative cost, thus reducing the over-all price tag still further.

20. Most important of all, the construction need not be of cement and steel, but of any available materials, beginning with bamboo and mud, which will, of course, reduce the construction cost of the units drastically, for in most developing countries, there exist age-old

indigenous systems of building, far more inexpensive—and more relevant—than the so-called “solutions” (prefabricated reinforced concrete panels etc.) currently promoted by many Indian architects and engineers.

21. Indeed, the advantages are considerable. And there are a number of additional benefits which accrue to this pattern of low-rise, high-density housing, whether one is speaking of self-help squatter housing at Lima, Peru, or elegant town houses in Greenwich Village in New York. These benefits include:

(a) A low-rise building has a much shorter construction period, so that the interest cost of capital tied up during construction is considerably less;

(b) The low-rise building is incremental, i.e., it can grow with the owner's requirements and his earning capacity. Eventually, the owner may want to add an additional floor or two, either for rental or for his grown-up children's families (this would have the additional advantage of increasing the housing densities, though it would entail a certain flexibility in the pattern of infrastructure provided);

(c) It has great variety, since the individual owner can design and build it according to his own needs;

(d) An individual building his own house is a highly motivated person; this motivation might possibly

engender an increase in savings *per capita* so that housing is built without sacrificing other national investment targets;

(e) It need not use high-priority construction materials. Multi-storey buildings must of necessity use steel and cement, commodities which are in extremely short supply in developing countries. On the other hand, the individual row-house can be constructed with non-priority materials (the recent advances in paper technology open up a world of new possibilities);

(f) Of course, if the house in its early stages is constructed of brick, mud and country tile, then it will not have a life span of more than 10 or 15 years—as compared with a reinforced concrete structure, which will have a much longer life span. But the impermanence of materials used in the early stages of construction is really an advantage, for after 15 years, when the economy improves, one might presumably have more resources to deal with this problem of housing. As Charles Abrams has pointed out, “renewability” should be one of the prime objectives of mass housing in developing countries, for, as the national economy develops, the housing patterns can change;

(g) Low-rise housing has considerable social and psychological advantages which have often been enu-

merated,<sup>15</sup> which is, of course, a crucial area of the problem.

22. It must be emphasized that this pattern of low-rise, high-density housing being examined here necessitates only a marginal increase in over-all city size. Unfortunately, most people associate low-rise housing with the kind of suburban sprawl one sees outside Indian cities, which, of course, is not what is being discussed. In its concentrated form, low-cost housing is the optimal and classic pattern of residential land-use, an age-old pattern which has been manifested in cities throughout the centuries. This is probably the main reason why, up to the Second World War, Bombay could attract a great number of immigrants without having to throw them destitute upon the pavements of the city. It is only in recent years that the municipal planning policies have swung away from low-rise buildings in favour of more sophisticated (and expensive) solutions, the additional cost of which is met, of course, by raising the selling price of the units. And in the current distorted land-use picture of the cities in India, it is very easy for the developer to command these prices.

23. It is, however, exactly this kind of exploitation which can be avoided by intelligent land-use planning. Too much time has been spent in a fruitless search for architectural and structural answers to the problem of low-cost housing, and they exist only to evaporate into thin air. Yet, if one looks around the developing world, one finds that there exists in each of these countries—in fact, there has always existed in each of these countries—houses at a price the people can afford. In other words, these countries do not really have a problem of low-cost housing; what exists is a problem of land-use planning. To determine rationally land-use priorities and allocations is the essence of the task one faces. And pointers to the solution exist—in the villages, at Benares, in Tokyo and in London (a city which is a prime example of many of the principles outlined in this paper and one which is still the most human and livable of all the great metropolitan centres of the West). No, the current lack of low-cost housing is not just the failure of the architectural answers; but, rather, and primarily, it is due to the fact that the planners have stated the question wrongly in the beginning. Their suicidal land policies have resembled a poker game in which the stakes are being continuously raised; today, they are surprised to find that they have reached the point when the vast majority of players drop out because they cannot afford the ante.

24. Considering that most of one's life is spent in cities, it is disquieting to realize how seldom one stops to ponder how varied the planning options might really be. Lionel March<sup>16</sup> calculates that just 250 of Ebenezer Howard's Garden City clusters would accommodate all

of Britain's urban population in the year 2000, in one third the urban area. The minimum residential plot would be 6 metres wide by 30 metres deep. March continues:

"Imagine the countryside developed by a grid five miles square. Now suppose the linear density along the route is 5000 persons per square mile (1.6 Km)—a high density but easily accommodated in houses and gardens. Then at one-mile (1.6 Km) intervals there would be functions to support 5000 persons and these could be reached by walking through the countryside or along the service routes. Within 10 minutes by bus or five minutes by car there would be facilities to serve 100,000 persons. In a quarter of an hour by car and 30 minutes by bus a regional centre for 500,000 persons. In such a network city all uses would be placed where they were best sited along the route. Uses would not be segregated. Public transport would serve evenly an even distribution of activities and population. All could live in the town at their front door and in the country at their back. . . . All could have a house. No one would have to live in a block of flats because of the present inability of land use planning to provide the right shape of plot for the right type of building."<sup>17</sup>

25. To optimize the total *per capita* cost of the system must of necessity involve also re-establishing land-use priorities in other areas of the city. For instance, the question may be asked at what point the acreage of green areas crosses the point of diminishing returns; or whether one would be better off providing the same quantum in other ways. The city of Delhi, for example, provides 1.5 hectares of green area per 1,000 inhabitants. This area is probably lower than that provided in most European capitals; and yet when one examines this figure, one finds that it works out to 15 m<sup>2</sup> *per capita*, i.e., 75 m<sup>2</sup> per family. It is indeed ironic that families in Delhi, festering in little hovels, should have 75 m<sup>2</sup> awaiting them along some monumental park, and, at the same time, one hesitates to give them a courtyard of 10 m<sup>2</sup> which they will really use.

26. As another example, in central Bombay, there are less than 0.10 hectares of green area per 1,000 population,<sup>18</sup> and this figure includes the green in traffic islands. Yet merely increasing the *maidans* (open spaces) is not necessarily the solution, for they are not used by the entire population, but only by certain age groups for cricket, football and other such games. No little toddler of 2 or 3 years would dare play here; nor does one see middle-aged couples using them for evening strolls. On the other hand, the pavement of the Marine Drive—which incidentally does not show up on the statistics—is one of the great community spaces of the city. It would appear that people love a promenade

<sup>15</sup> Jane Jacobs, *The Death and Life of Great American Cities* (New York, Random House, 1961).

<sup>16</sup> Lionel March, "Homes beyond the fringe", *Architectural Design* (London), vol. XXXVII (September 1967), pp. 434-436.

<sup>17</sup> *Ibid.*, p. 436.

<sup>18</sup> The high densities in most Asian cities are obtained, not because of high-rise buildings, but through the criminal omission of the green areas, social infrastructure etc.

along the sea; and, in fact, this is one activity which covers just about the entire spectrum of age groups in the city. In order to rehabilitate Bombay, one should, perhaps, strive not only to preserve the existing *maidans*, but to adopt plans and policies that would generate many more such promenades. These are the heart of the social life of a tropical or temperate city.<sup>19</sup> The Latin cities—Paris, Rome, Rio de Janeiro—have always understood this; hence, the wide boulevards with their broad pavements and cafés. (Perhaps one tree on the Boulevard St. Michel is worth half an acre of green in the Bois de Boulogne. It would be intriguing, and highly relevant, to try and quantify this.

#### MOBILITY WITHIN THE CITY

27. The question then arises, however, whether lowering the residential densities will disproportionately increase the average travel time and the travel costs, in particular, of the public mass-transport systems.

28. The question of mass transport is indeed important, as more and more cities, even in the developed world, are perceiving the advantages of giving public transport priority over private transport. In developing countries, of course, owning a private motor-car is a rather esoteric condition, and public mass transport becomes almost as crucial an urban prerogative as housing. Only about 2.27 per cent of the population of Bombay owns a motor-car.<sup>20</sup> To deny the average man mobility is to make him forfeit the city's greatest asset: communication.

29. A mass-transport system—whether a tram-car, a train or omnibus on a reserved track—is essentially a linear function. It only becomes viable in the context of a land-use plan that develops corridors of high-density demand. The distance that a person is willing to walk to the transit station depends upon the mode of transport and differs from country to country, indeed, very often from city to city.

30. In New Bombay, for example, even if each person were given an individual plot,<sup>21</sup> gross residential densities of 500 persons per hectare could be achieved.<sup>22</sup> Thus, 800,000 persons can be serviced along a double railway track 16-km long, with industrial jobs at one end and central business district employment

at the other.<sup>23</sup> The capital cost of this rail system comes to Rs 250 per family and the running cost to less than Rs 0.01 per passenger-kilometre; neither of these costs need involve a subsidy.

31. Thus, one sees that if the mass transport system is allowed to act as one of the primary generators of the structural plan,<sup>24</sup> then maximum efficiency and convenience can be achieved at a minimal cost *per capita*. Even though the figures previously quoted may increase (depending upon the residential densities employed, the positioning of the work centres and, of course, the cost structure of the transport systems themselves), and this increase might necessitate a partial subsidy of the transport system, it is still a proposition with considerable advantages. In effect, one would be subsidizing low-cost housing indirectly through a subsidy of the mass transport system, which might well be preferable to a direct subsidy of housing, as this contradicts the actual market value of the housing and leads, at least under Indian conditions, to illegal transfers of the tenements.

32. Since the essentially linear corridors generated by a mass transport system may impose too severe a constraint on site planning, it is usually advantageous to generate patterns from a combination of two or three compatible systems; thus, a hierarchy of transportation is set up, the interchanges becoming natural nodal growth points in the city structure. By combining complementary systems in this manner, one can open up more of the *hinterland* of the site<sup>25</sup> without being constrained within a narrow-ribbon development. Furthermore, the implementation of these various mass transit systems can be successively phased over a period of time as the city grows and each, in turn, becomes economically viable. Thus, beginning with a simple omnibus in mixed traffic, one can gradually build to electric trains on four or more tracks, without at any stage transgressing the cost/capacity constraints faced.

#### STRUCTURAL PLANNING

33. Thus, it is seen that by using the mass transit system to open up the site, one can probably keep the densities in the residential areas at near-optimum levels.<sup>26</sup> This, of course, calls for a kind of open-ended planning. What is needed is not a "frozen" master plan, but the definition of a series of growth options. Because of the organic, almost biological, nature of urban growth, it is counter-productive to postulate only pre-

<sup>19</sup> The continuous crowds on the streets of Bombay may not be merely due to the high densities in the city. Roads are only 8 per cent of the land use of central Bombay—compared with almost 40 per cent in Lutyen's New Delhi.

<sup>20</sup> Regional Transport Office, Bombay, by actual count.

<sup>21</sup> An area of  $4 \times 11$  metres, on which a house of  $33 \text{ m}^2$  can be built (in stages). This is considerably higher than  $6 \text{ m}^2$  which is the average area per household for the majority of the families in the old city, but much less than half the plot size that could be adopted in Western metropolitan centres for low-income housing.

<sup>22</sup> For New Bombay, a tolerable walking distance to the railway station has been estimated to be about 800 m (a walking time of from six to eight minutes), which establishes a *hinterland* of about 50 hectares on either side of the railway station.

<sup>23</sup> The structural plan of the city consists of three such spines, hooking around the central business district in an open-ended pin-wheel arrangement.

<sup>24</sup> See Arthur Ling, "Urban form", in *Planning and Architecture* (London, Barrie and Rockliff, 1967).

<sup>25</sup> Considerable developmental work is being done in the West on new transport systems which, in effect, also open up a wider *hinterland*—e.g., "dial-a-bus", where the omnibus first collects all the individual passengers from their houses before switching to a reserved track for the ride into the city centre.

<sup>26</sup> Doxiadis has said that for 1,000 years urban densities had stabilized at around 150-200 persons per hectare; cities only got into trouble when people started to "fiddle around" with them.

conceived fixed patterns. When one establishes a city, one is beginning a process. What is needed is a flexible structural plan which indicates probable nodal points. These nodal points, of course, will be primarily determined by the interchanges on the mass transit systems. Human settlements have always tended to locate at transport junctions, on a scale directly proportional to the importance of the junction. Thus, a natural hierarchy of nodal points develops, culminating in the city centre.

34. At these nodal points, higher densities can be allowed to develop for such specialized functions as offices, shopping and luxury apartments. The greater the densities, the more the need to separate vehicular and pedestrian traffic.<sup>27</sup> In recent years, there have been several proposals to exclude all vehicular traffic from the city centre, movement within the central business district being either on foot or by various forms of horizontal "travelators", moving chairs<sup>28</sup> etc.

35. The structural planning options open to the city will, of course, depend upon the regional transport pattern, topography of the site, breeze directions, existing pollution problems etc. Intermixing of work and residential areas is, in general, advantageous, as it not only makes for shorter journeys to work, but loads the transport system more evenly. (In fact, bending the transport pattern around a full circle, with work spaces evenly distributed, can very well double its capacity.) However, two important constraints may be involved: one is the pollution which may be generated by the industrial units; and the second is the interindustrial linkages which may work against such a dispersal.

36. With respect to pollution, one finds that whereas, in the developed world, urban pollution is principally the outcome of a high level of living (motor-car exhausts, industrial emissions, packaging disposal etc.), in the developing world, it is the low level of living that causes the problem. Here, a considerable portion of the pollution is caused by small wood cooking-fires burning all over the city, uncollected garbage<sup>29</sup> and human excreta.<sup>30</sup> These pollutants can generate health problems of epidemic proportions. In fact, if the density in the residential areas can be reduced to, say, 80-100 persons per hectare, it may become feasible to dispense with a central sewerage system<sup>31</sup> and to recycle the waste matter to considerable advantage (vegetable gardens etc.). Under Indian conditions, this plan would have the additional advantage of allowing the people a pattern of life to which they are accustomed, as though Mahatma Gandhi's vision of a rural India had an almost exact urban analogue.

<sup>27</sup> B. Rudofsky, *Streets for People* (New York, Doubleday, 1969).

<sup>28</sup> Brian Richards, *New Movement in Cities* (New York, Reinhold, 1966).

<sup>31</sup> D. Baste, *Planning for Ratnagiri* (1972).

37. The fact is that new towns work best when they are based on the natural life-style of the people. It is easy enough to adopt policies that help assimilate local people<sup>32</sup> displaced by the project (as in the case of the Santhal tribes at Jamshedpur). It is much more difficult to achieve this on a scale of an entire city population. Yet, this and other sociological aspects of the problem are of crucial significance. Too often, planners have unwittingly trapped people, as witness Chandigarh, where the social and economic status of a person is instantly identifiable by the sector in which he lives, and the whole town is locked into a geometrical hierarchy which is utterly feudal.<sup>33</sup>

38. Motivating people to participate in the city is all-important, and it involves much more than just the economic impulse. It could be something as simple as the right civic structure which could prove to be a decisive input in the "genetic code"<sup>34</sup>—the "DNA"—of a new city. If one goes back to the beginnings of Bombay over a century ago one finds that it never really had a formal master plan (it was established by a small group of people—perhaps two East India Company civilians and an army colonel—who made a few bold decisions and began a process of growth). But what the city did have, up to the beginning of this century, was the right kind of civic structure. In short, it had the right kind of mayor, who chose the right kind of city engineer who, in turn, put in the roads and the sewerage lines—usually in the right places. And this is far more important than having the right kind of master plan, but the wrong kind of mayor, city engineer and so forth all the way down the line. Now the civic structure that helped to create Bombay was very Victorian. It involves the whole paraphernalia and mystique of city fathers; a very paternalistic mystique which found a responsive parallel in nineteenth century Indian society. For, in the various castes and communities of Indian society, there were a number of elders and "leaders" who were eager to play this fatherly role. In modern Bombay, none of these kinds of city fathers are left; or if there are, no one is very interested in following them. Thus, Bombay is breaking down because the civic structure no longer relates to the social realities of the city. This is true of several cities throughout the world. Yet, the question may be asked how a civic structure relevant to the twentieth century is to be found. For this structure, indeed, will constitute a decisive element in the DNA of a new city. (For instance, while Bombay always had only one municipality, Calcutta had 28, and the resulting chaos has done

<sup>32</sup> There was considerable opposition from the local farmers to the land acquisition for New Bombay, which was largely overcome by extensive training programmes (including taxi-driving, tailoring, gardening and office work), plus the guarantee of a job in the new city.

<sup>33</sup> Victor d'Souza, *Social Structure of a Planned City: Chandigarh* (Bombay, Orient Longmans, 1968).

<sup>34</sup> Other important social inputs into the "genetic code" are hospitals, schools, universities etc.

more to ensure the disintegration of Calcutta than all the current efforts of the Naxalites and others.)

#### THE "GENETIC CODE" OF A NEW CITY

39. Though it is beyond the scope of this paper to discuss settlement patterns and optimal urban sizes, from the Indian experience,<sup>35</sup> it has become apparent that little towns in the middle of nowhere (with their high development cost *per capita*) are really a tremendous financial burden upon the industry or function they serve.<sup>36</sup> There really may be a stunningly simple reason why developed countries have large urban concentrations; it is probably the most efficient way to generate wealth.

40. Yet, the problem of generating a large viable centre within a developing economy is indeed a formidable one, especially since the job-generating inputs<sup>37</sup> (really the crux of the problem) are in short supply. In time, perhaps, techniques will be found for re-using some of these inputs. After all, certain inputs are more mobile than others and are, in that sense, re-usable. For instance, dock facilities, once set up, cannot be moved. On the other hand, a key function like that of the Government is highly mobile. Furthermore, government jobs have a high multiplier effect

<sup>35</sup> In India, more than 50 new towns have been built since 1947. These were usually single-purpose towns (steel towns, state capitals etc.) varying in size from 5,000 to over 100,000 population.

<sup>36</sup> These costs are usually added on to the sale price of the product; and even if (as in the case of the steel towns) they are subsidized by the Government, the citizen continues to foot the bill, if not as consumer, then as taxpayer.

<sup>37</sup> It is interesting to speculate on the relationship between the physical pattern of a city and its economic growth. Obviously, a land-use pattern that involves high-rise investments will exclude much of small-investment capital floating around in the "bazaar area" of the economy. Furthermore, to the extent that the "bazaar economy" is characterized by underemployment (as opposed to full-time unemployment in the "firm-type" capitalistic area of the economy), it is the more absorptive part of the city structure. This capacity for absorbing increased labour, sometimes called "involution", is found not only in developing countries, but within the traditional peasant agriculture; and it appears to provide, at least in the short run, a certain amount of stability to the socio-political system.

(estimated at five, in the context of New Bombay). Obviously, if new urban growth centres are to be generated, within the limitations of the economy and resources, then one must find techniques for re-using some of the key inputs several times over. As soon as a healthy and sustained growth is ensured, some of these ingredients could be remarshalled and used again. This would be rather like a technique for grafting trees. (Or, perhaps, a better analogy would be a travelling circus: the Government of a developing country pitches tent every 10 years and generates the process of urban growth; then it moves on.)

41. The important thing to remember is that this kind of growth has occurred in history. The British really created Bombay and Calcutta out of thin air. The Spanish manufactured Lima so that they could ship the gold back to Spain. It is interesting that these colonial Powers were really very decisive people. They knew that they would have to act quickly and forcefully in order to keep their empire going. It appears to be more difficult to get national Governments thinking in these terms. Yet, it is crucial that the techniques of urbanization should be invented. For within this decade, the countries of the third world must begin to plan their urbanization patterns as boldly as they plan industrialization today.

42. It is essential that these new urban patterns emphasize mass housing and mass transportation, so that one can completely bypass the whole cycle of motorization and de-motorization that the cities of the West have gone through. With the flow of migrants into the existing centres, the slums and uncontrolled settlements contain an ever-larger portion of the urban population: 33 per cent at Karachi and Calcutta, 41 per cent at Brasilia, as high as 80 per cent at Buenaventura (Colombia). Yet, through rational anticipation, it appears that one might be able to meet this growth by functionally restructuring urban configurations, and, through land-use policies involving large-scale acquisition, developing these areas with a minimal amount of seed capital. The concept of self-help housing already exists; there must now come into being the concept of, and the programme for, self-help city.

## RURAL DEVELOPMENT, DISPERSAL OF INDUSTRIES AND POPULATION REDISTRIBUTION: POLICIES AND EXPERIENCES \*

Ashish Bose \*\*

1. The growing concern about the environment has introduced a new dimension to demographic studies. The crisis of human settlement is no less acute than the crisis of population explosion and the need for controlling human settlement is as great as that for controlling population growth rates. Yet, in the massive literature on population, the attention given to human settlement is utterly inadequate. Demographers have usually relied on geographers to study the subject. Of late, however, rapid urbanization, increasing rural-urban migration and the consequent ecological problems have forced demographers to devote more attention to urban growth, internal migration and population redistribution. However, the perception of the problem of settlement is still heavily biased by an almost exclusive concern for metropolitan areas and big cities. It is still rare to find demographers studying the settlement pattern from the rural angle in spite of the obvious fact that the majority of countries are predominantly rural and most of them will continue to be so even at the end of this century. It cannot be denied that some of the environmental problems are most acute in the large cities, but the obsession with pollution problems in large cities tends to underestimate the urgency of such environmental problems as floods; deforestation, soil erosion and primitive sanitary conditions, and a host of allied problems in rural areas. This gives rise to the tendency in the common people to equate environmental problems with the pollution problems of big cities.

2. The chapter on "Problems of human settlements" in one of the pioneering studies on environment, by Ward and Dubos,<sup>1</sup> begins, "The first need is to take the strain off existing cities", and proceeds to give some figures indicating the deplorable housing condition in Indian cities. But one could argue with equal force that "the first need is to take the strain off rural areas—the strain of poverty, unemployment and economic and social stagnation". One could also give figures for the deplorable state of the productive base of the rural economy in countries like India.

3. An over-emphasis on the problems of big cities created by "the human avalanche" of migration, to use

the picturesque phrase of Ward and Dubos, underestimates the positive role of migration in relieving rural poverty. There is inadequate realization of the role of cities as reception centres for the rural poor in countries like India. The tendency to look upon rural-urban migration as a nuisance and urbanization as an evil, and to dream of pure air and the picturesque landscape in the countryside is to shut one's eyes to economic reality. This is not to deny the urgency of positive measures to regulate rural-urban migration. The popular view that as rural to urban migration is creating serious problems, such migration should be curbed, is an over-simplification. One should ask: serious problems for whom? Certainly not for the rural migrant in spite of all the hostilities of the urban environment. In fact, poverty and unemployment in rural areas drive the migrant to the city. Can one look upon the cities as the exclusive preserve of only those who are already there and ask for an internal passport system in the name of orderly urban development? As a recent study of poverty in India by Dandekar and Rath points out: "Urban poverty is an outflow of rural poverty. Hence action against poverty has to be initiated in the rural areas."<sup>2</sup>

4. Regional development has been put forward as the answer to most problems of unbalanced development of human and material resources, excessive metropolitan development, concentration of industries in a few areas, growing environmental degradation and other related issues. Yet, in spite of some significant contributions to regional science in recent years, the theoretical studies are still scanty. Besides, at the implementation level, regional planning usually becomes a political issue and not a theoretical tool for better national planning.

5. In a recent study of regional development in South and South-East Asia, sponsored by the United Nations Research Institute for Social Development, the authors point out:

"In spite of the agglomeration forces the geographic dispersal of industrial development is, rightly or wrongly, accepted almost everywhere in the Region as a desirable social objective. Unfortunately, decisions are based on very little factual cost benefit analysis of urban growth and patterns of decentraliza-

\* The original text of this paper (E/CONF.60/SYM.III/3) was submitted to the Symposium on Population, Resources and Environment, Stockholm, 26 September-5 October 1973.

tion. In fact, government agencies frequently attempt to induce the dispersal of industries by providing production facilities and urban infra-structure as well as fiscal incentives to new industries without understanding the forces involved. The much commented 'growth pole' theory, relied on to provide the intellectual framework for dispersal policies in some of the countries, unfortunately does not offer much policy guidance with respect to the *a priori* identification of potential growth centres.

"The problem is difficult, in part because there may be valid reasons for wanting to sacrifice some commercial profitability for the sake of other social objectives. In addition, there may also be diminishing returns to scale effects and genuine social costs which outweigh the benefits of agglomeration. Whatever the case, it is not possible, at least in the current state of the art, to provide universally valid general principles and guidelines for the determination of the optimal degree of concentration or dispersal."<sup>3</sup>

6. The introduction of the environmental variable makes the benefit cost analyses and other exercises more difficult and complex. This highlights the need for a series of theoretical studies on the human settlement pattern in relation to environmental problems which can systematize the different levels of interaction between population, resources and environment.

7. The empirical studies on internal migration and population redistribution are scanty not only in the developing countries, but in the developed countries. Concerning this subject, Hilde Wander comments:

"Contrary to policies regulating the international flow of migrants which have for many decades attracted the interest of social and economic researchers, policies affecting internal migration have seldom been the subject of systematic investigation . . . . Not only the impact of direct migration policies has largely escaped intensive analysis; it has also never been sufficiently studied how other forms of public policy, especially in health, education, social welfare or economic fields, or how the lack of certain social policies have indirectly influenced propensities and opportunities to migrate. Similarly, the backwash effects of such 'spontaneous' migrations have hardly ever been thoroughly reviewed."<sup>4</sup>

8. Here again, the introduction of the environmental variable will make such empirical studies more meaningful. The current state of knowledge on the relationship between urbanization and environment in different parts of the world is severely limited, however, by the paucity of data and systematic long-term studies.

9. To sum up, in the absence of adequate theoretical and empirical studies on the interrelations between

population, resources and environment, much of the thinking is guess-work and speculative, the solutions offered tend to be the obvious and the simplest, and the implementation of whatever policies are put forward is by and large ineffective and incapable of meeting the challenge of the crisis of human settlement. Other obstacles are the lack of an effective administrative machinery to tackle environmental problems; political interference often responsible for ignoring technical solutions, especially in regard to locational policies; and the high cost of preventing environmental degradation.

#### RURAL DEVELOPMENT AS A DETERRENT TO RURAL-URBAN MIGRATION

10. It is important to realize that the success of urbanization policies in developing countries depends to a considerable extent upon the success of modernization of agriculture and transformation of rural areas. Under conditions of rapid population growth and agricultural stagnation, the flow of migration from rural to urban areas cannot be stemmed merely by restrictive policies. The best deterrent to migration in such a situation is accelerated rural development.

11. Gunnar Myrdal, while analysing the problems of agricultural development in South Asia, calls for "fundamental changes in the traditional agrarian structure and in the attitudes of the people living and working within it".<sup>5</sup>

12. A common feature of the developing countries in Asia is excessive dependence upon agriculture. One of the primary objectives of development planning is to reduce this dependence on agriculture and evolve a more diversified occupational structure. In many of these countries, the persistence of a colonial economic structure and a rigid social system in the face of rapid population growth makes the task of economic development very difficult. This results in structural stagnation. When the economy falls into this trap of stagnation, there is no migration of labour from agriculture to industry and the proportion of the agricultural labour force remains more or less constant.

13. In a paper on population growth and the development of a dual economy, Sato and Niho<sup>6</sup> present a useful theoretical analysis of such stagnation. Their analysis is of particular relevance to such countries as India, which possess a fairly advanced industrial sector, but, at the same time, have a large proportion of workers still in the backward agricultural sector. These authors observe:

"If the actual growth rate of population tends to exceed the maximum sustainable rate, without governmental measures of population control, the society will fall into a trap of stagnation. If, on the

<sup>6</sup> Ryzo Sato and Yoshio Niho, "Population growth and the development of a dual economy", *Oxford Economic Papers*, new series, vol. XXIII, No. 3 (1971), pp. 433-434.

other hand, some means are found to suppress this population explosion, the society can achieve the steady process of development. The society can, *alternatively*, achieve modernization if it can raise maximum sustainable level of population growth rate higher than the present level of population growth by improving technology in agriculture and/or by changing production conditions in agriculture. . . . The results we have obtained emphasize the importance of positive population policies as well as the policies promoting technical change in the society.”<sup>7</sup>

14. The population problem thus cannot be viewed merely in terms of an accelerating growth rate resulting from a persistently high birth rate and a rapidly declining death rate. The population problem in the developing countries of Asia is much more a problem of structural stagnation on account of a persistently high proportion of the working force depending on traditional agriculture. Considered from this point of view, improvement in agricultural technology and the modernization of agriculture not only will have a bearing on agricultural productivity but will release forces of modernization which will affect the attitude towards family size.

15. It is curious that in the massive discussions on the population problem in recent years, so little has been said about the relevance of land reforms to the population problem. In countries where a predominant majority of the population depends upon agriculture and the major share of the national income is derived from agriculture, it is but natural that any demographic policy which seeks to influence fertility behaviour must take note of the basic economic reality. Unless the social and economic life of the rural masses is touched by policy measures, economic and social stagnation cannot be broken.

16. The development of rural areas *per se* will not necessarily lead to reduced rural-urban migration unless rural-urban disparities between wage rates, income levels and employment opportunities decrease over time. It is not always rural poverty which encourages out-migrations from rural areas. For example, in the developed countries of Europe, rural-urban migration is motivated by higher incomes and increased availability of non-agricultural jobs. But, as a study by the United Nations Economic Commission for Europe (ECE)<sup>8</sup> points out, a certain threshold in income level has to be reached before agricultural workers leave the land. It has been suggested that the incentive income ratio between agriculture and industry is 60 per cent or less in the case of farmers, but as high as 80 per cent in the case of agricultural hired labourers. This study contends that:

“The income factor as a determinant for leaving agriculture has, however, weakened because of gov-

ernment farm policy to increase farm incomes . . . . In recent years . . . government agricultural policy has concentrated on increasing production, investment and incomes in agriculture. This policy has led to more favourable relative income levels in agriculture than before. Farmers receive a considerable measure of price or income support through guaranteed prices, import restrictions and direct grants or subsidies.”<sup>9</sup>

17. Another factor generating rural-urban migration is mechanization of agriculture. There are striking differences in the situation in the developed and developing countries. The ECE study observes:

“It is, however, difficult to say to what extent mechanization of farm operations and a transfer of workers from agriculture to industrial and service occupations have been the cause and to what extent the effect of rising agricultural productivity. The occupational shift is, therefore, clearly integral to the process of economic development and a necessary adjustment to increased productivity in agriculture itself and in the economy as a whole. The movement has been taking place gradually but by now agricultural labour is so small that rural-urban migration has little effect on the employment market where the agricultural worker represents only a minor source of new recruitment for expanding industry and services. This again strikingly contrasts with the situation in developing countries where migration from rural areas is of such a magnitude and character that it constitutes a disturbing factor for a balanced development of the national economies.”<sup>10</sup>

18. Lastly, it is important to bear in mind that throughout the world young people migrate from rural areas to cities, though not necessarily for economic reasons. Unless the image of rural areas is improved, rural development alone will not be an effective deterrent to such migration. As Marion Clawson rightly points out:

“The ambitious farm youth frequently seeks to leave farming, for a city occupation, not only because its economic rewards may be greater but also because its social prestige will be greater. . . . In all too many countries, agriculture is a field of economic activity of second or lower rank, socially speaking. Such an attitude greatly impedes agricultural development, and greatly complicates a coordinated development of agriculture and of urban centers. National planners and leaders must adopt measures to increase the social standing and the public regard for agriculture, at both farming and professional levels, if agriculture is to advance as much as is economically possible.”<sup>11</sup>

19. While it is possible to argue that rural development is the best deterrent to excessive rural-urban

<sup>7</sup> *Ibid.*

<sup>11</sup> Marion Clawson, “Modernization of agriculture and urbanization”, paper presented to the Rehovot Conference on Urbanization and Development in Developing Countries, 16-24 August 1971, p. 6.

migration, the argument cannot be stretched too far. It may be true that people, by and large, will not opt for the big city if they have a choice, and, indeed, they may indicate their preference for rural areas; but a detailed probe often reveals that what people really want is to enjoy the benefits of both city and rural life and it is doubtful if they would really opt for rural areas which are far away from metropolitan centres. For example, a survey of residents in Wisconsin (United States of America) shows their preference for smaller places within commuting distance of a metropolitan central city: 70 per cent of the respondents said they would prefer to live near a metropolitan area, whereas only 54 per cent actually lived in such an area. Commenting on this, the report of the Commission on Population Growth and the American Future observes:

"We do not know if the results of the Wisconsin survey reflect national attitudes. If they do, it means people want the best of both worlds—the serene and clean environment of rural areas and the opportunity and excitement of the metropolis. Perhaps it is not accidental that much metropolitan growth in fact occurs in peripheral areas with a semi-rural environment. Ironically, people moving to such areas typically find that they soon lose their more desirable aspects—semi-rural areas rapidly become suburban."<sup>12</sup>

20. The search for a more satisfactory habitat has led to the advocacy of small towns and growth centres, which, it is argued, could serve as bridges between the big cities and the rural *hinterland*.

#### DISPERSAL OF INDUSTRIES AND DEVELOPMENT OF GROWTH CENTRES

21. The general trend of thought throughout the world is in favour of dispersal of industries, development of new growth centres in medium-sized and small towns, establishment of new towns, market towns and service centres, improvement in rural housing, creation of better employment opportunities in rural areas, improved mass transportation and a host of other measures to counteract the lopsided growth of metropolitan areas and big cities. While the philosophy of such measures cannot be challenged, the economics of these measures remains controversial, especially in the developing countries.

22. The economics of the development of new growth poles and new towns still remains a neglected field. Reference has already been made to a recent study of regional development in South and South-East Asia, which laments the lack of cost benefit studies supporting the policy formulations. A study sponsored by the Asian Development Bank concludes:

"Realistic policies towards industrial location and associated urban growth are among the most difficult

<sup>12</sup> United States of America, *Population and the American Future*, the report of the Commission on Population Growth and the American Future (Washington, D.C., Government Printing Office, 1969), p. 34.

for Southeast Asian governments to adopt because they run counter to deeply held political beliefs and against strong vested landownership interests . . . . It is . . . difficult for provincial politicians to accept that the development of a limited number of industrial centres with populations upwards of a million is far more economic than the spread of industry throughout a country . . . . Appropriate investment in urban development will not only provide a direct stimulus to industrial growth by solving the land bottleneck, bringing labour close to the factory, and increasing the market both for intermediate products and final consumer goods, but will also make a contribution to that growth of small-scale industry and employment which Southeast Asian countries are so eagerly seeking."<sup>13</sup>

23. This view will be challenged by many and certainly by the exponents of the growth-pole theory.

24. A case is often made for the development of small and medium-sized market towns. The argument runs:

" . . . Once rural incomes rise, both spending and saving will grow. The resulting investment can, in turn, set transformation in motion, and the greater the number of central places where the intensified activity occurs, the greater the vigour, continuity and acceleration of the process of transformation. The critical places are the market towns and small cities."<sup>14</sup>

25. This approach was challenged by an Indian economist, who argued:

"(our) main contention . . . is that while developments in the physical infrastructure of an economy can bring about quantitative and even some qualitative adjustments in the super-structure, they cannot induce basic structural changes . . . .

"Now, what are the basic reasons for the extremely unsatisfactory state of affairs of India's rural economy, more so West Bengal's? Is it due to lack of roads, electricity, warehousing or rural industrial estates? In all these spheres, particularly rural electrification, West Bengal is one of the most backward amongst the different States even of India. But can it, therefore, be concluded that if more of such infrastructure facilities are built up, the condition of rural Bengal will change radically?

"The answer to the above question will clearly be in the negative if we bear in mind the existing facts regarding the pattern of land distribution and the deadly grip of the evil trinity, viz, the landlord, the money lender and the speculative trader, over our rural economy.

"Thus 70 per cent of the peasants in West Bengal own less than 18 per cent of the total land while 4

<sup>13</sup> Asian Development Bank, *Southeast Asia's Economy in the 1970s* (London, Longman, 1971), p. 240.

<sup>14</sup> E. A. J. Johnson, "The integration of agrarian, commercial and industrial activities in functional economic areas", in National Council of Applied Economic Research, *Market Towns and Spatial Development* (New Delhi, 1972), p. 73.

per cent of the peasants at the top own 27 per cent of the total land. In what way will the condition of the smaller peasants, with holdings of less than 2.5 acres, improve from extension of electricity, warehousing, transport linkages with servicing and market centres and so on? They will hardly be able to take power either for domestic or for irrigation purposes because the cost of electrical implements and installation will be prohibitive for them. They will not have sufficient holding capacity to enable them to store produce at warehouses in order to get higher prices. And of what use will be the roads to them? Not owning any implements, and not producing much surplus they will hardly need access to a market town either for purchasing spare parts and servicing of machines and implements or selling products.”<sup>15</sup>

26. There is no doubt that in India, in the context of the “green revolution” and the possibility of generating agricultural surpluses, there is need for market towns; but obviously the first step should be to make the “green revolution” a success rather than plan for 14,000 market towns, as suggested by some experts.

27. The growth centre concept is often seen as a substitute to radical relocation policies. For example, Preston Andrade observes: “The focus . . . on a community composed of a growth centre and a group of dependent villages has the advantage of great flexibility. It avoids the necessity for such radical relocation policies as have been adopted in parts of Eastern Europe and it provides for changes required by future development.”<sup>16</sup> Andrade points out that much depends upon the political system and what is possible in Poland is not possible in India. For example, Poland “is simply eliminating all settlements of less than 2,000 population, enlarging some and relocating the people. . . .”<sup>17</sup>

28. The implications of the urban growth-centre concept have been neatly summed up by Lloyd Rodwin as follows:

“The fact that the size and the characteristics of the activities are ambiguous, the costs and benefits uncertain, and the factors which determine the location of successful centers not at all clear does not discourage use of the concept. On the contrary, its ambiguity contributes to its suggestiveness as well as to its misuse. And, despite pleas for more rigorous definitions, the situation is unlikely to change much until we know more about the sequences or stages by which growth and urban development spread to lagging regions and more about the type of urban pat-

terns and policies that exert the maximum influence on lagging hinterlands.”<sup>18</sup>

29. This brings the discussion to the allied issue of industrial estates. Several countries have programmes for developing industrial estates as instruments of regional dispersal policy. Like the growth centre concept, the case for industrial estates is strong on logical grounds, but the actual working of these estates reveals the practical difficulties of this approach. “Analysis of the ‘Industrial Estates’ programme in India and Singapore brings out sharply the obvious truth that in a market economy success or failure of an enterprise depends primarily on market conditions.”<sup>19</sup>

30. Obviously, it is not fair to compare India with Singapore. The study itself points out that the industrial estates of Singapore are comparable to the successful “trading estates” in the United Kingdom of Great Britain and Northern Ireland, where “the uncertainties of transport and communication were never as great as in the rural areas of India”.<sup>20</sup> Another study of industrial estates in India points out: “It is no longer a secret that industrial estates located on the outskirts of metropolitan centres have succeeded while others in the countryside have almost invariably failed.”<sup>21</sup>

31. For the purposes of this paper, it is not industrial estates as such which are the matter of concern, but their effectiveness from the point of view of the dispersal of industries. The conclusion arrived at by Lefebvre and Datta-Chaudhuri merits attention:

“In India, as in some other South East Asian countries, the programme was saddled with the additional responsibility of creating employment on a large scale and particularly by policies attempting to influence the choice of techniques (labour intensity) in the direction of those used in traditional small scale industries. Even though the policy was not effective, it may have restricted in practice the choice of product and sometimes also the choice of markets. The structure of the market for products usually associated with small scale industry does not help the new industrial entrepreneur, who wants a regular buyer for all his products. A co-operative marketing or state-trading organization might perhaps provide necessary support. But in the present situation entrepreneurs on industrial estates have strong reasons for wanting to be on the fringes of the established industrial sector of the larger economy. As a consequence, the effectiveness of the ‘Industrial Estates’ programme as an instrument of regional dispersal is rather limited in an under-developed country, although it may play a valuable role in promoting general industrial de-

velopment by encouraging new entrepreneurs and helping the acquisition of new skills.”<sup>22</sup>

32. A pertinent question that arises is whether accelerated rural development, development of growth centres, market towns, service centres, industrial estates etc. can check the primacy of large cities. In his statistical study of the location of industries and population, Colin Clark<sup>23</sup> gives examples of countries where the primacy of large cities has been maintained or has increased or decreased. He also talks of “oligarchies” in the context of urban growth. Briefly, his conclusion is as follows:

“Russia . . . apparently made efforts to check the primacies of [the] largest cities; but even in planned economies, this does not seem to be an easy task. Russia shows a remarkable lack of industrial cities of middle-ranking size. . . .

“Switzerland, Netherlands and Belgium are countries which have made conscious and successful efforts to check the relative growth of their larger cities. . . .

“One may perhaps apply the term ‘oligarchy’ to countries, such as Japan, India and Brazil, where the towns over 100,000 population have a bigger share of the total urban population than would be expected from the straight line relationship [between population of city and cumulated number of cities above specified population] but where, at the same time, the primacy of the leading city is kept in check. Still more striking is the oligarchy of five leading cities in Australia.

“In Germany, we find a curious situation which can only be described as a mixture of oligarchy and counter-primacy.”<sup>24</sup>

33. It is important to keep in mind that the primacy of large cities is sustained by non-economic factors also. Clark observes: “It is easy to distinguish the factors which are making for the increasing primacy of Paris—the concentration of so much political, administrative, educational and cultural authority there. Similar causes, deriving from the political and social structure of the country, not economic causes, are probably at work in Latin America, Greece and other countries.”<sup>25</sup>

34. The experience of Paris is very relevant. A study of governmental measures for the promotion of regional economic development in different countries of the world has the following to say about the French experience:

“The example of France has important policy lessons for other countries as well.

“As first, the most obvious fact was the excessively rapid growth of the Parisian agglomeration, and the aim stated more or less explicitly was the halting of this growth or even the reversing of the process. It was soon recognized, however, that this was neither

possible in view of the expansion of population and the relative development of the secondary and tertiary sector of the economy, nor desirable if Paris was to continue to play its role as capital to the full and, on a European scale, to balance the large population centres of the neighbouring countries. The Paris region has furthermore already been organized and a development programme established in line with the growth expected. The efficacy of the measures taken to encourage regional development should not therefore be denied simply because the development of the Parisian agglomeration has continued.”<sup>26</sup>

35. To come back to the relevance of this discussion from the point of view of environment, it may be pointed out that policies which suggest development of cities and towns in a specified population size group (say, cities of 300,000 or towns of 50,000) tend to oversimplify issues. In real life, one has to contend with cities of all sizes, so environmental problems must also be considered in cities of all sizes, no matter how serious the pollution problems are currently in the largest cities. The following observation by a British environmentalist deserves close attention:

“Perhaps the most radical policy would be to accept that within half a century or thereabouts the best qualities of urban life will be the goal of most people. Instead of bemoaning the drift from the land and dissipating resources into propping up faulty rural systems, it would be more positive to plan constructively for the variety and number of urban settlements needed to fulfil human aspirations. Such a policy should seek to ‘get ahead’ of the drift by diverting available resources into the development of strategically planned settlements and relating these to the management of rural resources.”<sup>27</sup>

36. To sum up, the preoccupation with size of cities is likely to be futile in the absence of policies influencing the settlement pattern as a whole.

#### POPULATION REDISTRIBUTION

37. In a recent review of policy aspects of population redistribution in the United States of America, P. A. Morrison observes:

“The dynamics of migration have an important bearing on how public policies might influence redistribution of population. The net effect of migration ordinarily is small, relative to the much larger (but, for the most part, self-balancing) gross flows into and out of a locality. But the flow into an area—the ‘pull’ of economic attraction—is potentially responsive to policy measures. Population redistribution could, in theory, be influenced by policies that

operated on the inflow side of migration to affect the *destinations* of moves.”<sup>28</sup>

38. An important point made by Morrison is that about public policies arbitrarily influencing the economic effectiveness of certain areas. He maintains that “any effort to modify population redistribution must include a thorough assessment of these activities, which are themselves essentially ‘hidden policies’ for redistribution.”<sup>29</sup>

39. Morrison refers to “spontaneous growth centers” (SGCs) defined as metropolitan areas that are drawing migrants at unusually high (net) rates.

40. In the Union of Soviet Socialist Republics, regional science experts have designated “spatial production combinations” (SPCt) at different levels which include “spatial production complexes” (SPC). M. K. Bandman observes that:

“Since every SPC is a link of the national economy as a whole, we may consider as optimal only that complex with which the state programme of producing output by branches of specialization and creation of living conditions necessary for the people is fulfilled with minimal social labour expenditure.”<sup>30</sup>

41. For the economy of an SPC, the infrastructure of non-material production spheres is of great importance. As Bandman explains:

“As productive component of the infrastructure we consider construction and energy bases, transport facilities, engineering communications and servicing facilities, water supply installations and other elements used jointly by the whole complex and all the industries. Cultural, instructional, health, trade institutions, public restaurants, passenger transport and other elements of the service sphere as well as housing fund, administrative and science organizations form the social part of an SPC infrastructure. The infrastructure is formed in accordance with the general level of development of productive forces in the complex, and location of its objects is determined by specific conditions of functioning of the rest of the economic elements of an SPC and its population as well as demand for them.”<sup>31</sup>

42. In Japan, the problem of rural depopulation has been engaging the attention of planners, particularly since 1967, when the new name “Kaso” (excessively sparse) was applied to less densely inhabited areas and depopulated areas. The concern for Kaso areas is mainly based on the recognition that rapid out-migration of the young adult population from rural communities is

resulting in an increasing percentage of old population in rural areas, decline in family income, decrease in the number of working members, increase in the cost of cultivation and relatively low productivity.

43. In the context of environment, it is necessary to take note of the consequences of rural depopulation. As Toshio Kuroda asserts:

“There are serious implications of air pollution, water pollution, traffic congestion, inadequate housing, and noise in the great urban areas. On the other hand, problems of maintaining social, economic and cultural functions are being aggravated in rural depopulated areas. Taking into account the urgency of ensuring the people’s health and welfare and the necessity of using rationally the extremely limited land surface, a new comprehensive environmental development must be devised.”<sup>32</sup>

44. A problem allied to rural depopulation is that of dispersed population. René Eyheralde estimates that in Latin America, approximately 35-40 per cent of the rural population lives in dispersed settlements (under 20 people). The difficulty of supplying public services to such a population should be obvious. In the great majority of cases, neither electricity nor drinking-water is available. Systems for eliminating waste are rudimentary. In such a situation the grouping of the population becomes an efficient tool for the effective organization of rural societies. The Latin American programme of rural urbanization is relevant to the study of new forms of settlement. But as Eyheralde cautions, “Unfortunately there do not exist yet in Latin American countries enough valid examples of the creation and functioning of agricultural villages within this continent; it is, therefore, advisable to be cautious in their indiscriminate promotion.”<sup>33</sup>

45. A point of view has been expressed that urban housing tends to receive a higher priority than rural housing in developing countries in spite of the fact that “rural housing cannot be ignored if Governments wish to reduce the drift of a large number of people from rural to urban areas.”<sup>34</sup> But the trend of rural-urban migration does indicate the strong pull of cities in spite of the acute housing shortage in cities. It is doubtful if improved rural housing alone will make a significant change in the volume of rural-urban migration. To say this is not to argue against accelerated programmes of rural housing, but the relevant issue here is whether rural housing can stem the tide of migration. It is well-known that young men and women are reluctant to stay in villages and they are the first to migrate to cities. It

<sup>34</sup> C. B. Patel, “Rural housing in the Economic Commission for Asia and the Far East region and experimental work in India”, in *Rural Housing . . .* p. 32.

is doubtful if the lack of good housing in the rural areas, as such, motivates them to leave their villages. Unless there are adequate employment opportunities in rural areas, the drift to the towns and cities is inevitable. In India, in the very first five-year plan period (1951-1956), an experiment was made in remodelling an entire village because it was felt that in the rural areas environmental sanitation, water-supply and the disposal of human waste were more important than the mere construction of houses. This experiment was not successful. It was realized that improvement in housing conditions has to be related to improvement of the economy of the village. The villagers found it difficult to repay the loans advanced by the Government because "the general productivity and especially that of agriculture had not increased."<sup>35</sup>

46. Thus, a rural housing policy, to be successful as an instrument of a policy of population redistribution, must be part of an agricultural policy designed to accelerate agricultural productivity and rural incomes.

47. Even in the developed countries of Europe, it has been recognized that rural housing problems have to be dealt with "not so much as part of a housing policy."<sup>36</sup>

48. In the industrial countries, housing policies should be linked more effectively with industrial policies. An eminent architect and planner of environment asserts:

"The large American new communities of recent years... demonstrate another inadequacy of the private entrepreneur: his failure to combine industry and housing. Park Forest did start out by earmarking an area for industry, but it did not bear fruit. There was no particular leverage available to the builders with which to attract industry, and the profitable creation of housing absorbed their attention and energies. A genetic reason for such failure may be that characteristically open-planned industry cannot compete for land at the prices that privately produced houses can command, particularly with the bait of resale at a profit. Thus again we are back to the proposition that as long as land is a freely disposable private commodity and speculative profit is a basic factor, large-scale logically related development is not going to take place, though the volume of development may prove large."<sup>37</sup>

49. Limits of space precludes the consideration of several other related issues, such as community development programmes, resettlement schemes, rural works programmes, issues in transportation and regional planning. There has been no discussion of numerous programmes of incentives, tax relief and other fiscal concessions given to industries to move out of congested urban areas or establish new units in neglected areas,

<sup>35</sup> *Ibid.*, p. 34.

depressed pockets etc. The literature on these aspects is massive, and it is possible to make an inventory of a series of specific measures concerning locational policies and measures directed towards influencing the out-migration from rural areas. It would be pointless to do so, however, because each country is unique in its own way and no standard solutions can be prescribed. Yet there is a consensus in both the market economies and the centrally planned economies, and in the developed countries as well as in the developing countries, that comprehensive regional planning offers the best solution to the problems under study. It is important to realize that consideration of single problems and single solutions will not succeed. What is needed is a holistic view and total solutions. A comprehensive approach to regional development has been advocated in several United Nations studies. In this context, particular reference may be made to the United Nations study<sup>38</sup> of regional development, which is the outcome of a series of visits paid by teams of experts appointed by the United Nations to various selected regional development projects. Such studies based on actual field-work provide a valuable supplement to theoretical models and empirical analyses.

#### CONCLUSIONS

50. There is a tendency throughout the world for environmental problems to become equated with pollution problems of big cities. However, this is still a rural world; and it is, therefore, necessary to get a proper focus by paying more attention to problems of rural environment. Otherwise, the talk of quality of life would refer only to the *élite* and not to the masses.

51. There is no doubt that, in the metropolitan areas and big cities throughout the world, problems of environment are most acute and the need for containing the "human avalanche" of migration is great, but it does not follow from this that rural-urban migration is an evil. In fact, such migration has played a positive role in relieving rural poverty. Unless there is acceleration in rural development and a reduction in rural-urban disparities, and unless the image of the rural areas improves, such migration is bound to persist.

52. The advocacy of growth centres, market towns etc. often over-emphasizes the spatial aspects at the cost of economic aspects; and, therefore, programmes of dispersal of industries, by and large, tend to be ineffective.

53. The concern for development of cities and towns of a particular size group tends to oversimplify issues. Controlling things at the urban level without touching the rural reservoir of population is bound to be fruitless.

54. While the need for rural housing is great, it is doubtful if improvement in rural housing will by itself slow down rural-urban migration. The crucial factor is employment.

<sup>38</sup> *Selected Experiences in Regional Development* (United Nations publication, Sales No. E.70.IV.14).

55. Different countries have adopted different programmes to tackle the problem of excessive urban growth and lopsided regional development, but one of the crucial issues is: whether the primacy of big cities can be contained. There are very few success stories. A large number of economic as well as non-economic issues are involved. It is possible to argue that an increase in the primacy of big cities is not necessarily an index of failure of policies of dispersal of industries, development of small towns and regional planning as such.

56. A better management of space and population is possible through more sophisticated techniques of regional planning, but regional planning becomes a political issue at the level of implementation. The success of regional planning would appear, therefore, to depend upon the political will of decision-makers.

57. The population problem in developing countries is not merely the problem of an enlarging gap between the birth rate and the death rate, but also a problem of stagnation of the social and economic structure.

58. There has been an over-emphasis on the growth of population and a neglect of the distribution of population both in developed and in developing countries.

59. The recent energy crisis calls for a restatement of the population problem, taking adequate note of such critical issues as mass transportation, the impact of the increasing cost of transportation on the dispersal of industries and the possible slowing-down of suburbanization, as well as a host of related issues. There should also be a greater concern for human settlement and alternative strategies for modifying the settlement pattern directed towards improving the quality of life.

## HUMAN SETTLEMENTS: MAN-MADE ENVIRONMENTS\*

### *United Nations Environment Programme*

#### DEVELOPMENT AND ENVIRONMENT

1. In fashioning their first shelters, human societies have set in motion a dynamic and potentially highly productive process of adapting their natural habitat to their needs and liking. But when they built the first settlements in the more fertile river basins of Africa, Asia and Europe (a mere 10,000 years ago), different societies took the first tentative steps on the long road of development. Struggling first to survive and then to develop, societies have applied increasingly complex technologies and, in the process, degraded the natural environment in a very short time. Two interpretations of this phenomenon are possible. The more obvious one is: a slow biological evolution and socio-economic development; and then suddenly man destroying the natural habitat that sustains him. Or, the current condition can be seen as an entirely new stage of human and environmental development: man supplementing nature and forming, by degrees, an environment presumably more efficient as an agent of economic development; and, at the same time, also more convenient as human habitat. Total accommodation to and dependence upon the natural environment has shifted gradually to partial and increasing "control" of the environment. By deliberately applying the sciences and the technologies societies already possess (and, it is hoped, working with nature rather than blindly destroying it), one may be able to improve the natural habitat. The essential relationship to be understood in this context, then, is the interaction between the "controlled" man-made environment and the natural environment which man must respect in order to survive and develop.

2. Social progress and economic growth, population, the natural and man-made resources, environment and the development of human settlements are closely connected and crucially important factors in the development process. Their interaction determines the direction and the pace of development. But the way in which different societies use these processes in their development and distribute the benefits obtained through "deliberate" development, and what attitude they assume towards the environment are determined by the value systems and the political processes of decision-

making that operate in their respective cultures. As a consequence, a unified socio-economic, environmental and administrative-political approach to planning and to plan implementation, appropriately suited to these value systems and processes, should be adopted when and where development objectives, policies and strategies, or development projects and programmes are being conceived, realized and managed. Before such an approach can be applied, however, certain obsolete economic concepts and certain emerging policies still accepted as inescapable constraints to development need to be dispelled:

(a) *Historical determinism*: a notion that all development must follow the patterns evolved in the societies that are currently industrialized and affluent, both "free-enterprise countries" and/or "market-controlled economies"; as well as those "centrally planned" and/or "Government-controlled", even though many of their social and environmental phenomena are counter-productive from the point of view of human progress and the human qualities of life;

(b) *Economic determinism*: a notion that, in the context of development, economics is an "exact science" like those dealing with nature and has its "immutable laws" which man seeks to understand and perhaps harness, but cannot change; that "economic efficiency" motivates and guides development, which, in turn, must produce economic benefits as great and as fast as feasible, regardless of the social cost, human hardship or environmental damage, so that the material benefits of development should reach more people in the long run;

(c) *Technological determinism*: a notion that effective use of modern technologies requires ever-greater agglomerations of production services, people and facilities in order to draw benefit from the scale of operation, increase the economic effect of development, broaden the distribution of goods and reduce the cost of management, even though these objectives tend to impair the human qualities of life and turn the once "free" external economies into increasingly costly "externalities";

(d) *Ecological determinism*: a notion that the ecological systems of the earth, created by evolutionary changes, are the only viable ones, and since their absorption capacities and recycling tolerances for man-made pollution are absolute and finite, they cannot interact productively with man-made environments; and

\*The original text of this paper (E/CONF.60/SYM.111/20) was submitted to the Symposium on Population, Resources and Environment, Stockholm, 26 September-5 October 1974.

<sup>1</sup> See P. Spreiregen, "The skin of the earth", *Way Forum, Special Issue on the City* (Brussels), No. 63 (December 1966).

that there is, owing to this incompatibility, an absolute and finite tolerance of the earth's total ecological system for man-made development as represented by industrial societies;

(e) *Centre-periphery conflict*: a notion that for the sake of economic efficiency, there must be, in the course of development, a concentration of production and people, of economic power and business, of national wealth and political power in the dominant cities and regions in individual countries and in the dominant countries of the world; that this concentration must occur at the expense of the "marginal people", the "peripheral areas" and the "developing countries" as a phase in the long-term process of national and world-wide economic development which will, in due course, "spread" around the globe;

(f) *The equilibrium mechanism*: a notion that the "free market" as a self-regulating socio-economic system is endowed with built-in controls (in the form of a continuous interaction between supply and demand), which can and, indeed, do correct automatically any imbalances within and among the different factors influencing development (such as investment, production, distribution and consumption); and, therefore, societies do not need to regulate these processes for the purpose of diminishing the differences between the rich and poor of a country, or to reduce the growing gap between the affluent countries and those locked in a vicious circle of underdevelopment.

3. In the continuing process of intensive interactions of man-made environments with the natural environmental systems, the dynamic role of man's societies has been, and continues to be, the essential factor of change. The institutions of government; the technology, law and economics; a society's culture and its values are man-made and therefore also capable of being changed by man.

4. Human settlements are man-made environments in which the rapidly urbanizing society creates or impedes new economic capacities and enlarges or frustrates the human qualities of life. National urban and metropolitan systems have also become, by degrees, the link among the essential and often conflicting processes and problems of our different societies and cultures, the *milieu* in which they confront each other, accommodate to one another or clash. For better or for worse these conflicts must be resolved in their metropolitan and urban settings.<sup>2</sup> To escape further degradation of life and environment, these man-made systems

<sup>2</sup> The following remarks by Maurice Strong, from his address at the Meeting of Experts, United Nations Conference-Exposition on Human Settlements, Vancouver, 8 May 1973, are appropriate: "Within 30 years the human race will have crossed a fateful and astonishing historical interlude. Man will be living for the first time in a predominantly urban plant... [Communities of more than 20,000 people] will be growing at twice the over-all rate of population growth. Cities with more than 2 million may be growing twice as fast again... The majority of new settlements will be in the poor, still developing lands where the resources... are grossly and pitifully inadequate... The changes that are looming could come

will have to be so organized and managed that their immediate and cumulative effects on the natural ecosystems are compatible with the ecological tolerances of these systems. Then, human settlements and economic growth may become less "eccidal". However, any meaningful and effective action in the urban field would have to be based on coherent national (and, in many instances, international) policies and strategies for growth as elements of pivotal significance for development in both the economic and the human and environmental sense. And this is true of both the developed and the developing countries. The ensuing constructive interaction of man-made and natural systems may only then reduce and repair damages already done and enhance long-term environmental development.

#### THE GREAT MIGRATION OF THE TWENTIETH CENTURY

5. In the 1950s, about 50 million people were being added to the world population. The current rate of accumulation is 75 million a year. In 1930, it was about 30 million and it is expected to reach about 125 million by the year 2000. Then the earth may be inhabited by from 6 thousand million to 7 thousand million people. Two out of every three will most probably be urban dwellers. Socially and economically viable urban environments would have to be built, therefore, in less than three decades for 13 times as many people as in the previous 150 years; and the rate of construction would have to average at least 40 times that of the recent past. According to United Nations estimates, the phenomenon of an "over-rapid" urbanization<sup>3</sup> due to an ever-increasing pressure of rural migration is now compounded by a structural change in its destination (see tables and the figure given below). First of all, the addition to the rural population, living in settlements with less than 20,000 people, may equal or even slightly surpass, between 1960 and 1980, that of the preceding 40 years. Secondly, the increments to the urban population, those living in settlements with 20,000 people or more, may be considerably larger in the current 20-year period than they were in the previous four decades. Thirdly, the "big-city" population, those living in agglomerations of 500,000 people or more, is expected to rise in the same period from 96 million to 725 million. Nearly all of the increments in the world's rural and small-town population would occur in the developing countries. At the same time, the trend of accumulating a rapidly growing share of the world's urban population is also expected to continue in the developing countries.

with such speed and on such a scale that they threaten to overwhelm us—sometimes before we can even define their nature... I am convinced that if there are eco-disasters in the next decade or so, they are likely to occur in the large cities of the developing world."

<sup>3</sup> "Over-rapid" in terms of the growing discrepancy between the very fast rate of urbanization, the relatively low rate of economic growth and the still slower rate at which urban employment opportunities become available to the poorly equipped rural migrants.

TABLE 1. WORLD POPULATION 1920, 1960 AND 1980

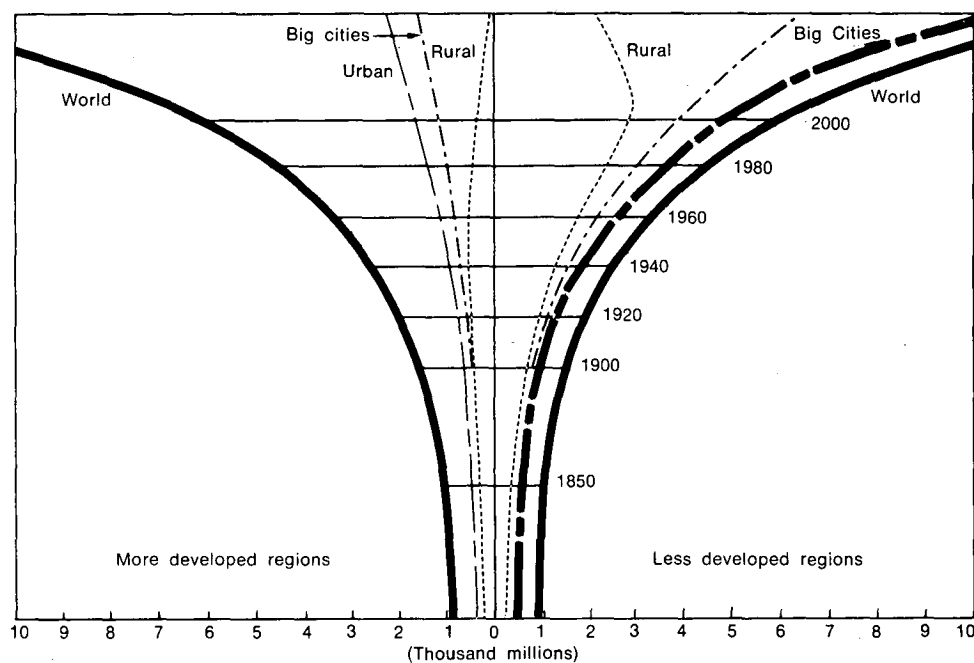

Type of settlement	1920	1960	Increment	1980	Increment
World population	1,860	2,994	1,134	6,264	1,275
Rural and small town	1,607	2,242	635	2,909	667
Urban	253	752	499	1,360	608
(Big cities)	(96)	(351)	(255)	(725)	(314)
More developed regions	672	977	305	1,189	212
Rural and small town	487	544	57	516	22
Urban	185	433	248	623	190
(Big cities)	(80)	(212)	(132)	(327)	(115)
Less developed regions	1,188	2,017	829	3,080	1,063
Rural and small town	1,120	1,698	578	2,343	645
Urban	68	319	251	737	418
(Big cities)	(16)	(139)	(123)	(398)	(259)

SOURCE: "World urbanization trends, 1920-1960", *International Development Review*, No. 1 (United Nations publication, Sales No. E.68.IV.1), pp. 9-20. The developed regions include all of Europe, Japan, Northern America, the Union of Soviet Socialist Republics, Temperate South America, Australia and New Zealand. The developing regions include East Asia (excluding Japan), Middle South Asia, South-west Asia, the Caribbean, Tropical South America, the middle American mainland, all of Africa and Oceania (excluding Australia and New Zealand).

6. The following facts emerge from these estimates. In 1960, the developed regions of the world had a rural population of 544 million and an urban population of 433 million, of which 212 million were in large cities. In the developing regions, the net additions to the 1960 population (2,017 million) may amount by 1980 to 645 million rural and 418 million urban inhabitants, with

259 million in the big cities. Thus, from 1960 to 1980, population growth in the developing regions is expected to exceed the total 1960 population in the developed regions, with the overage appearing in the big-city population with an increase of 259 million, compared with an increase of 115 million in the developed regions; and in the rural and small-town population with an increase

Urban and rural world population, by more developed and less developed regions, 1850-2000

SOURCE: "World urbanization trends, 1920-1960", *International Development Review*, No. 1 (United Nations publication, Sales No. E.68.IV.1), pp. 9-20. The developed regions include all of Europe, Japan, Northern America, the Union of Soviet Socialist Republics, Temperate South America, Australia and New Zealand. The developing regions include East Asia (excluding Japan), Middle South Asia, South-west Asia, the Caribbean, Tropical South America, the middle American mainland, all of Africa and Oceania (excluding Australia and New Zealand).

of 645 million, compared with an increase of 22 million in the developed regions. By 1980, the urban population of the developing regions would be nearly equivalent to the 1960 urban population of the developed regions—418 million compared with 433 million.

7. The grim implications of these projections for the developing regions of the world are these:

(a) Between 1960 and 1980, the developing countries would have to provide at least tolerable levels of living, public services and facilities for more than 1 thousand million new citizens, in addition to improving the grossly inadequate conditions of some 2 thousand million people in the rural areas and small towns;

(b) Between 1960 and 1980, the developing countries would add 418 million to their current urban population, meaning that they would have to create in 20 years urban environments and productive employment for nearly as many people as have accumulated in the cities of the developed regions of the world over the past 150 to 200 years or more;

(c) The big-city population in developing countries would increase between 1960 and 1980 by nearly 260 million (which is considerably more than the number of people who now live in the large cities of the more developed countries) and create in 20 years metropolitan agglomerations equivalent in size to those that existed, in the 1960s, in the developed countries.

8. To sum up, the developing countries would have to provide employment and a tolerable environment to as many big-city dwellers as currently live in such metropolitan cities of the developed world as Paris, London, Moscow, New York and Tokyo; and the huge urban industrial complexes, such as the Eastern Seaboard megalopolis in the United States of America, the mega-region in north-western Europe and the Tokaido Corridor in Japan; and provide urban services and facilities for as many people as currently inhabit all urban areas of the developed countries. These are unprecedented tasks surpassing by far anything done at any time, in any place, by any known society. It is entirely inconceivable that they can be accomplished with the economic capacities, technologies and the material and capital resources now accessible to the developing regions of the world from any quarter.

#### CURRENT TRENDS IN URBANIZATION

9. The current rapid expansion of cities and the explosive growth of metropolitan agglomerations in the developing countries are relatively new phenomena. As industry becomes the source of livelihood for progressively larger populations, people tend to move in pursuit of a better life, an aspiration common to all mankind. In this era, the city embodies the basic conditions for the fulfillment of this aspiration. It therefore attracts with elemental force those whom insufficient land and conditions of tenure could barely sustain in the past and whom new agricultural technologies now make "superfluous" at an accelerating pace. But it also

attracts with equal force the "redundant" people from the smaller cities and the towns bypassed by modern industrial development. The current migration is the largest and most important the world has ever experienced, not only because it is universal, but because it conditions most directly the distribution patterns of production and people, and because it has unleashed a chain of drastic changes around the world.

10. Economic and social factors have motivated the rural-urban migration in the past and they continue to motivate it now. There are, however, fundamental differences in the two situations. The industrial revolution of the nineteenth century in Europe and North America (and the more recent ones in some other countries) proceeded at a relatively moderate pace. Not without shock, to be sure, nor without hardship for the emerging industrial worker. In the main, the market has regulated economic development. Industrialization and urban growth occurred in the most advanced areas. And world trade favoured the new industrial countries. As cities grew, a new urban structure gradually took shape. Now, the headlong rush to the cities of Africa, Asia and Latin America is most massive and rapid in their least affluent areas. Their natural resources are still underdeveloped and the tools of production and capital resources remain grossly inadequate. Currently, these differences are becoming even more pronounced. In the more developed countries, industrialization and general economic growth still appear to create new jobs in step with further urbanization. Indeed, many highly industrialized countries must now import labour. However, the developing countries are already "over-urbanized" in the sense that their industries and related activities cannot employ all the young men and women who reach working age. Nor can they employ all the rural people who must migrate to cities. Economic and social problems and problems of government and management multiply as masses of uprooted rural people, unskilled and poorly educated, converge on the capitals and metropolitan cities.

11. In the developed areas of the world, the urban and environmental crisis has taken the form of "megalopolitan" development, in general an unplanned, unanticipated and unwanted concentration of activities, structures, services, things and people in gigantic urban industrial complexes. And in the developing regions of the world, a relentless and chaotic agglomeration of people and poverty goes on and on in huge, amorphous metropolitan regions expected to accumulate by the end of the century 15 million or 20 million people, or even 30 million or more. Here the explosive expansion is less due to the "pull" of economic growth and improved human conditions, than it is due to a massive flight of rural people from misery, hunger and disease. Each of these regions is an incipient "megalopolis"—less the productivity and resources available to the developed countries. Yet, the crisis must be seen also as a manifestation of technological and economic growth which promise abundance but which challenge the ability of

the world's societies to accept change and use the immense new productivity truly to improve the human condition everywhere.

12. Available evidence indicates that metropolitan regions, rather than the small towns and cities of intermediate size, will continue to grow rapidly. The difficulties so far connected with metropolitan regions and the "megalopolis" will also grow progressively more acute in the immediate and near future, unless, of course, the highest priority is given in terms of resources and human capacities to resolving the urban crisis through investment policies stimulating more manageable forms of settlement.<sup>4</sup> The long-term total impact of urbanization is highly positive. The city leads in industry, incomes and culture. If planned for comprehensively on the regional scale, it could also become an effective means of eliminating existing disparities between town and country. Instead of spending scarce resources on attempts to contain rural people in their marginal subsistence, practical measures are needed now to facilitate urbanization in carefully selected locations.

13. The traditional ways and communities are disintegrating under the impact of urbanization, industrialization, mass communications and an expanding world market. The urban services and facilities are already unable to satisfy the rapidly growing human, social and cultural needs of their citizens, even in the highly industrialized countries. But the real threat to the environment is not the current rapid growth of popula-

<sup>4</sup> Urbanization usually tends to continue at varying rates until the urban-rural ratios reach about 4:1. Then the process usually slows down, until land, employment and mechanization reach ratios capable of creating a sufficiently high productivity in agriculture, thus securing for agricultural workers' families incomes comparable to those already attained in the city. Only 3 per cent of the population of the Netherlands depends upon agriculture for its livelihood. Their cultivation is highly efficient and productive. By the end of the century, this figure may drop to as low as 1 per cent. In the United States of America, the figure is now about 5-6 per cent and is decreasing.

tion nor the more intensive application of new technologies. As has been stated, it is rather the continuing concentration of the means of production and of economic and political power in dominant areas and in dominant countries. These difficulties are then compounded by the quest for economic growth *per se* and short-run individual and corporate gain, regardless of the long-term investment interest and welfare of the wider community and the country.

#### UNDERDEVELOPMENT AND RESOURCES

14. The world's known natural resources are unevenly distributed. Capital resources and technology, their essential counterparts in the development process, have assumed in recent history even more unbalanced patterns. Illustrations of this phenomenon are that less than one third of the world population lives in the more developed countries and only one seventh in their urban industrial areas; that agriculture tends to be less advanced in the developing countries, where it is still one of the chief sources of livelihood; and that the gap between the living conditions in the industrialized countries and the remainder of the world continues widening (see table 2).

15. The worse physical phenomena of underdevelopment are concentrated in metropolitan agglomerations; but the resources available to the developing countries to deal with the crisis are extremely limited. According to a recent analysis,<sup>5</sup> the position of the developing countries is worsening. For example:

(a) The developing countries represent more than two thirds of the world population, but their gross national product (GNP) totals only 12.5 per cent of the world total. Consequently, the one third of the

<sup>a</sup> Including the USSR.

world population living in the more developed parts disposes of seven eighths of the global GNP;

(b) The gap is rapidly widening. The ratio of *per capita* income of the developing countries compared with the developed countries was 1:6 in 1900, 1:7.5 in 1930, 1:10 in 1960 and 1:14 in 1970. In the year 2000 it is expected to be 1:25;

(c) The *per capita* income of the 26 least developed among the developing countries compared with a group of four highly industrialized countries (namely, Canada, the Federal Republic of Germany, Japan and the United States of America) was 1:40;

(d) In the period 1966-1970, the *per capita* income in the developing regions of the world amounted to \$210; but the average yearly increment in *per capita* incomes in the developed regions was, in the same period, \$207. How disadvantaged the people are in the developing countries is also evident from the fact that in 1971, 10 multinational corporations have added in their operations values of \$3 thousand million or more. This amount is higher than the gross national product of at least 86 States Members of the United Nations.<sup>6</sup> Furthermore, 38 corporations (most of them multinational) accumulated in 1970 in sales alone \$3 thousand million or more, an amount reached in terms of gross national product by not more than 60 countries.<sup>7</sup> Only 19 countries had a gross national product higher than the \$28.3 thousand million realized in sales by the first ranking multinational corporation.<sup>8</sup> On the other hand, in 1970, the two leading industrial countries spent \$78 thousand million and \$65 thousand million, respectively, on their defence establishments. Of all the countries in the world, only nine (including those two) were able to accumulate such amounts in gross national product in the same year.<sup>9</sup>

#### A NEW SOCIAL STRUCTURE

16. In most countries, development manifests itself in two separate processes that coexist in an exceedingly loose relationship. The first consists of a set of large "productive" projects involving only small areas of the country and benefiting, in the short run, only a small part of the country. They are expected to build the country's infrastructure and industry, and to make available more equally the benefits of the wealth thus amassed in the long run. The second process is, in fact, a struggle for survival until such time as large-scale development matures and becomes operative and adequately productive. It encompasses a variety of programmes, mostly social in nature. For instance, "community development" has been combined in some cases with agricultural "extension" to increase food produc-

tion for the growing urban consumption. Some rural people have thus begun to participate in the national development effort as both producers and consumers. In other cases, handicrafts and cottage and small-scale industries have been regrouped in villages and towns, and organized as partially mechanized undertakings. They were able to produce for the growing urban markets some of the badly needed consumer goods for which no modern large-scale industry existed. Rural and small communities became considerably more attractive in the process, and dormant resources began to contribute substantially to general development.

17. Such programmes are obviously useful, but their effectiveness is limited in the long run and the rural masses continue to migrate to the cities where development goes on with more certainty for the future. This "spontaneous" urbanization is, indeed, the principal means by which the economic and social benefits of development can reach increasingly larger sections of a country's population. Under conditions of underdevelopment, urbanization often takes the form of "invasion" and "squatting" on vacant land and illegal construction of "shanty-towns". This form of urbanization is now accepted in many areas as being unavoidable. A whole new doctrine of "moral justification" and "legality" of squatting and of "borrowing" utilities is beginning to emerge. New zoning practices and dwelling standards are also being formulated and enacted in order to bring housing costs closer into line with the economic capacity of the "marginal" people. In itself the phenomenon of squatting is a progressive step. The provisional community surely is not a slum in any strict sense of the term.

18. A high degree of co-operation and planning goes into preparing "invasions" and building squatter towns. Political action and a great deal of collective bargaining and negotiation go into securing land tenure and obtaining communal services and employment. "Marginal man" really cares for his community and participates in its affairs most actively. Yesterday's "ignorant peasants" are learning quickly how to manage their community democratically, with their own families' shelter and livelihood as incentives. The possibilities of a squatter town becoming a stable community are all there. But decline and decay are equally possible. Owing to a lack of positive and constructive support by the "authorities", the *barriadas* begin to change from "incipient" communities to slums. Wherever the marginal migrant goes as transient or a permanent settler, he has undergone a radical change. The "push" away from a declining rural life combines with the "pull" of the city to change his outlook and aspirations. As "urban man", he has moved from the traditional landlord-peasant relationship to a new, as yet uncharted, social environment of the squatter town (often by way of the city slum). He now joins with others to promote his and his family's interests collectively.

19. This new social structure is co-operative in nature. With its strong reliance on self-help, self-

management and direct action, it represents a new condition in urban affairs that could also be used as a new development tool, particularly for tackling the many problems of "marginality" by means of community and collective action. Instead, futile aspirations are being promoted. For example, "individual home-ownership" through "savings and loan" institutions at the cost of one quarter or more of the family budget—a device conceivably useful when family incomes are more or less adequate to meet the other essential needs after paying high housing costs, but economically inapplicable and therefore socially meaningless in the developing countries. Much could be learned in this connexion concerning workable approaches, methods and techniques, through pilot projects which would be economically feasible and socially acceptable in terms of the motivations and values of the cultures within which they are meant to operate. These approaches should be designed, however, to bring together citizens and Governments in a real partnership in the political process of conceiving and realizing local urban development programmes as part of a national policy and strategy of deliberate urbanization, thus relating settlement patterns to industrialization, agricultural reconstruction and environmental development.

#### PLANNED DEVELOPMENT

20. The most often-stated objectives of national development are social progress and the improvements of the human qualities of life, and the generally accepted instrument for their achievement is economic growth. But social progress, the increased ability to satisfy human needs, is not an automatic consequence of economic growth. To obtain it, a society must allocate an appropriate share of the wealth it acquires to social development. Indeed, dissatisfaction with the blind pursuit of exclusive economic growth as the almost exclusive motivation for development has led gradually to a more equal distribution between economic growth and social progress in current national development planning.<sup>10</sup>

21. The interplay of the socio-economic activities generated by different societies in the course of past development, together with the settlements they built in the process of development, have produced in recent times a rapid degradation of the man-made physical and social environment and the natural ecological environ-

<sup>10</sup> The concept of gross national product (GNP) is now suggested to be replaced or at least supplemented by the concept of national economic welfare (NEW) as the "corrected" version of GNP—corrected (a) to "subtract from the conventional contribution these non-material disamenities that have been accruing as costs to our economy whether or not they have been charged against the industries and activities that caused them", and (b) "to add in items irrationally excluded from GNP (such as housewives' services in the house, value of expanded leisure and so forth). It is up to us, the public: if we will it we can give up half a percent of conventional GNP yearly growth, in order to achieve perhaps an extra quarter of a percent rate of NEW growth. And a good bargain many of us would judge such a trade off." P. A. Samuelson, "From GNP to NEW", *Newsweek*, 9 April 1973.

ment. It is these concerns that have caused countries to focus attention on problems of the environment and growth, specifically in terms of human settlements. It follows that to achieve its social objectives, a society must plan for an equitable distribution of the social benefits it can offer; and to maintain and enlarge the human qualities of the environment, it must respect the ecological tolerances of the environment to absorb man-made development. These are, therefore, the main concerns of human settlements.

22. In this context, development planning can be defined as both: (a) a model of an intended situation with respect to socio-economic activities, their location and linkages, and the land, structures, landscape and installation needed to house them; and (b) a programme of co-ordinated action with respect to the legislative, financial and administrative measures required to negotiate the transition from the present situation to that represented by the socio-economic environmental model. This dual definition implies a commitment to a concept of development through economic growth (in the quantitative sense) and through social change (in the qualitative sense). It also requires a continuing interaction and total integration of the two streams of development planning, namely, the construction of a technical (socio-economic and environmental) model, and the formulation of a political (legal, fiscal and administrative management) plan of action for its implementation.

23. Recent experiences in "deliberate" (or planned) development have demonstrated the fallacy and gross inadequacy of using traditional abstractions (like national averages for incomes, production and consumption) as quantitative development indicators, and the outright danger of current attempts to "quantify" the human and environmental qualities of life in physical terms alone. The geographical areas of a country differ in terms of their natural and man-made environments; their physical, economic and technological resources; the people and skills, their social structure and institutions, the rate of their productivity and levels of living, and the state of their health and education. The totality of these elements, some quantifiable, others not, account for the apparent uniqueness of each region.

#### THE REGIONAL APPROACH

24. Once these regional variations are recognized, national development strategies must try and strike a balance between two extreme positions: (1) to equalize conditions in all areas as soon as feasible conceivably at the expense of total national growth; or (2) to favour areas most likely to grow rapidly in order to maximize national economic product and generate, in the long run, progress everywhere.

25. Planners and policy-makers are becoming increasingly aware of the need for both economic and social progress. They are also beginning to acknowledge the importance of settlements for both. The concept of settlements and planning for their development must be

seen, therefore, as a regional orientation. Human settlements include both the actual areas and locations of residential communities and all the other systems that sustain them. A settlements area, then, would be more than a city or the housing sectors and neighbourhoods within it. It would include the economic, cultural and environmental systems which sustain it; the surrounding agricultural regions which supply its food and the transportation and communication systems and the utilities which support it.

26. Many development options are available for societies. Settlements and habitat, as conceptualized here, would appear to imply some sort of regionalization policy. And this implies projecting economic, social and physical environmental development in a given area, over a given time and, presumably, also for the benefit of the region's people, in addition to promoting national growth to which all regions contribute. In the process of regional development, viable locations are taken up by specific "programmes" and "projects", requisite linkages among them projected, and a suitable framework established for projects of national significance, as well as for those based on local aspirations, initiatives and resources.

27. The wide gap between the stated national goals and actual development in real, local situations could thus be bridged. Planned regional development tends to resolve conflicts among the many "sectoral" projects and programmes concerning land and location or the use of scarce resources; conflicts arising from the sequence and rate of their implementation; or conflicts opposing man-made development and the ecosystems affected by it.

#### REGIONAL DEVELOPMENT PLANNING

28. The "region" emerges as the physical, economic, social and institutional environment in which local growth potentials can be mobilized as part of, and in tune with, national development strategies. Whether this process is productive or counter-productive, from a society's point of view, will depend, in general, on whether regional growth can be induced where it helps, and stopped, in turn, where it may harm man or nature. Several propositions emerge from this recognition:

(a) The process of regional development can be regarded as the cumulative effect of a complex system of interacting development processes controlled or influenced by governmental and non-governmental interventions and by collective and individual decisions made at the local, the central (national) and the intermediate (or the regional) "levels". Planned co-ordination and integration of these interventions and decisions are apt to influence the interaction among investment projects and investment programmes, thus accelerating (or, if necessary, retarding) the pace of realization of different economic, social and cultural development targets;

(b) A regional approach in development planning can facilitate a meaningful "disaggregation" of the

national plan and its sectoral components; or promote the assembly of local programmes, plans and projects into larger, more manageable entities; or guide regions with special problems or potentials; or again, identify "growth poles" and implant new ones in strategic locations of developing areas. In either case, regional planning can promote the objectives of national development by judiciously combining the inputs from central sources with local resources, aspirations and action for a better total effect;

(c) The concept of planning would have to shift, therefore, from a predominantly sectoral (agricultural, industrial, educational etc.) to a comprehensive approach by integrating and adjusting to one another the sectoral developments in a given geographical area, both public and private. This does not mean, however, planning for all sectors in one place, in every detail and at the same time. It has as its objective, rather, intersectoral integration within critical areas in which related developmental factors interact through mutual accommodation, thus making their interplay more productive in terms of total development; the ability to mobilize latent resources, reduce the demand for scarce resources or cause less hardship to citizens;

(d) Consequently, comprehensive regional development planning would tend to assume in future a highly dynamic role of identifying development possibilities, and stimulating, guiding and controlling development in harmony with national objectives and strategies as well as the capacity of ecosystems to absorb such development. As a means of co-ordinating regional and interregional development efforts, it adds to sectoral and intersectoral co-ordination of activities the dimension of geographically defined development, relying on actual resources, people, institutions and infrastructure. The regional planning bodies are bound, therefore, to assume in the future greater responsibilities in the field of deliberate development. And the competence and ability of the central bodies in "interregional planning" will need to be increased, particularly with regard to their functions allocating investment resources to the different regions.

29. It is for this reason that comprehensive regional development has become in many countries an essential tool in implementing national objectives in the vital areas of industrial development, agricultural reconstitution, the restoration and improvement of the environment and the distribution of human settlements. As such, it is also an instrument for promoting human development throughout a country and a more equitable distribution of the means of production and welfare, thus providing for the requisite social, economic and geographical mobility of the people.

#### SETTLEMENT SYSTEMS PLANNING: THE CITY-REGION CONCEPT

30. Planned redistribution of "external economies" in a given region (through suitable adjustment of its

settlement system) could therefore also mould development processes into novel social and environmental patterns that would attract not only the rural migrant, but new employment opportunities; draw benefit from size yet avoid excessive concentration, make urban amenities more accessible to rural people and bring "nature" closer to the urban dweller. To be "productive", growth (as a factor of increasing the gross national product) requires technical and economic efficiency, an increasing agglomeration of activities and people in a given geographical area and a network of settlements to serve these aims. Historically, the settlement systems of the different societies have evolved, therefore, patterns designed to maximize the potentials for economic growth.

31. To realize a more equitable distribution of social benefits and the new human qualities of life that economic growth makes possible, the existing settlement networks must be adjusted accordingly. Making such an adjustment now, however, for social and human concerns can be justified also by the long-run economic gains that would be realized through greater attention to human needs and social progress. Furthermore, it is the same settlement system where the often adverse social and environmental consequences of a region's development and the "finite" capacities of the ecological systems to absorb them, meet and interact. Consequently, the settlement system of a region (or of a country) could assume the dual highly productive role of providing needed environments for efficient socio-economic development, and safeguarding the compatibility between these man-made environments and the ecological tolerances of the wider geographical regions concerned.

32. Carried to a logical conclusion, such an approach leads to the concept of "city-region"—a composite, polycentric system of separate but interacting urban centres (both specialized and diversified), of industrial zones and intensively cultivated areas, of centres of leisure, learning and culture, and of protected lands, all blending into their wider ecological regions. Man can enrich and develop these regions by judiciously applying science and technology in agriculture, industry and building, mobilizing and developing in the process the often latent local resources, aspirations and the people, and mobilizing also the social and economic potentials of the agglomerations of all sizes making up the existing settlement systems.

33. The city-region system is composed of a great variety of economic, social, political and environmental phenomena reacting upon each other ceaselessly. Any plan or projection of such a "mega-system" must encompass at least the following major systems:

(a) A social system to further the development of man now become highly productive, disposing of vastly more time and resources for his own development, more thoroughly informed, and, therefore, also better prepared to participate meaningfully in making decisions concerning his own and his community's welfare;

(b) An economic system to further the application of

science and technology in developing a "growing productivity of man and machine", and an equitable distribution of material well-being made possible through creative participation of citizens in the planning and realization of society's economic growth and human and cultural development;

(c) A political system to further the identification and setting of goals and strategies, and the means and methods of development in a continuing dialogue between planners and administrators, and the citizens, through due political processes and a true participation of citizens at all levels of decision-making;

(d) An environmental system to further the development of human settlements within larger ecological regions (ecosystems) as the physical framework within which economic and social capacities are being multiplied and the human qualities of life enlarged, an environment in which man intervenes as a creative builder, not a despoiler of nature.

34. To facilitate a meaningful participation in the dialogue and interaction within and among these four systems, a highly sensitive process of planning and monitoring is needed. This system would record, assess and integrate rapidly and effectively into all phases of planned development the potentials and consequences of new technologies and the resulting multiplication of industrial and agricultural productivity, as well as the human need for continued growth and development in dignity and freedom.

35. If so conceived and practised, comprehensive development planning of regional settlement systems could become a truly dynamic instrument of humanizing development and if transforming, at the same time, the current "guessing game" of forecasting on the basis of "current trends" (often misnamed "the planning process") to coherent action-oriented development planning. "Master planning", city by city, would then be replaced by comprehensive development planning of wider socio-economic and ecological regions with their urban agglomerates interconnected by means of "super-rapid transit" and "total communications", interacting with each other, with their own non-urban areas and with other city-regions both near and far. This type of comprehensive development planning could equally serve as an instrument for: (a) locating socio-economic activities where they will be most productive; (b) maintaining the balance between their adverse effects and the capacity of the ecosystem to recycle them; and (c) distributing more equitably throughout the country the social and human benefits created by such development.

#### ELEMENTS OF A VIABLE URBAN POLICY

36. In these circumstances, a redefinition of the concept "city" as a socio-economic, physical and political entity becomes necessary. A broader concept suggests itself as a closely interconnected and interacting "open" system of both diversified and specialized centres. Within a city-region system, any developing

centre or area can become the starting-point of planned development. In some cases, the objective may be the requisite concentration for economic growth and social welfare. At other times, it may be the loosening of urban agglomerates for higher efficiency or simply for enlarging the human quality of life. The city-region can take any shape and structure that geography, technology and human ingenuity can produce. But its main characteristics must always remain an unqualified flexibility and a capacity readily to respond to continued growth and to rapid social change.<sup>11</sup> What is suggested here, then, is not an image of the future city, but the formulation of ground-rules for a continuing dynamic process of unified and coherent socio-economic, environmental and political development of regional systems, both as part of national and international development and as a viable framework for planned local development.

37. The concept of city-region ultimately implies comprehensive development of extended areas in multi-centred urban systems which are efficient economically and desirable socially. Such development will also require new departures in professional training and research, especially with regard to collaboration and communication among the different disciplines involved. Joint research-training projects would tend to bring together the professions concerned through an understanding of their respective roles and contributions to comprehensive development planning. Citizens-at-large are the ultimate beneficiaries of development, and their participation in the setting and attainment of goals should therefore be secured. The press and other mass media play a most important role in facilitating understanding and acceptance of plans, as well as the understanding and acceptance of the hardships that inevitably accompany development.

38. Some scholars have combined the "biological" and the "sociological" approach to development planning of "human communities", analysing the complex interaction of people, their environment and their activities.<sup>12</sup> Others regard "the region" as the proper environment for the efficient accommodation of a greatly enlarged concentration of people and activities inhabiting "megalopolis".<sup>13</sup> The concept of "city-region" as discussed here is related to both these approaches. It differs from both, however, in that it establishes ground-rules for a process of a productive interplay among the main streams of development (rather than producing a "regional" or a "community" plan) as a means of

creating a human condition that can improve progressively as a result of economic, social and environmental development interacting upon each other, as well as a result of their cumulative contribution to such improvement. The great challenge for rapidly industrializing societies, then, is the need to mould, with the aid of contemporary science and technology, a socio-economic, physical and political environment that is worthy of human achievements and of the potentialities of an emerging affluent society.

39. The city-region concept offers itself as a viable approach to fashioning such environments. The principal issue for the developing countries, then, remains to assess the appropriate share of resources they must spend for social and environmental development in connexion with, and as a basis for, industrial and agricultural growth. A related issue for developing countries is how to make "deliberate" urbanization a main approach in the planned development of settlements and an essential element of their national development strategies. The principal issue for the developed countries, however, is how to negotiate a real change in the pace of action and replace welfare programmes under impressive labels of "urban renewal" and "slum clearance" or "social housing" by a concerted attack on all aspects of urbanization on a scale sufficiently large to make an impact on their national economies and to give impetus to local and regional growth. In either case, settlement systems must encompass agglomerations of all viable sizes, from hamlet to metropolis and the city-region, which are themselves made up of interacting systems of centres of different sizes.

40. The practice of seeking economic growth at all cost has already led to excessive concern with the variable and often elusive demand on the world market, rather than national needs. As a result, the pace and the patterns of urbanization in developing countries are often a direct result of the demand for certain primary goods in the highly developed countries. When external resources are sought for such development, however, the stark limitations imposed by the concept of economic efficiency are compounded with political and ideological issues. And this restricts even further the access to resources needed to enable the developing pre-industrial countries to put to good use their own natural resources and human capabilities for their own benefit. Unless current trends can be reversed, the already overcrowded and congested metropolitan agglomerations of the developing countries will become less and less manageable as agents of development and less and less suitable as places in which to live. However, judicious location of infrastructural projects and industry within a comprehensive regional planning framework could spearhead a productive harnessing of the pace and patterns of urbanization.

41. Industrialization and agricultural reconstruction should be planned, therefore, comprehensively, region by region. They should be adjusted to each other and suitably matched with infrastructural and environmental

<sup>11</sup> For a more detailed discussion of the "city-region" concept, see Ernest Weissmann, "Planning and development of the metropolitan environment", in Simon Miles, ed., *Metropolitan Problems—International Perspectives*, Intermet Metropolitan Study Series (Toronto, Methuen Publications, 1970), chap. 13.

XXXIX (August 1963).

development programmes. The positive forces of urbanization could then contribute to national development. Industry is often called the "engine" of development. The developing countries look to it, in the first instance, as the principal means of attaining adequate levels of production; and, afterwards, as a means of maintaining continued economic, social and cultural progress. Indeed, industrialization offers the key element in their struggle to break out of the vicious circle of underdevelopment; to begin closing the large and rapidly widening gap between the growth rates of their population and their economies; to create the needed means of resolving the multiplying problems of urbanization and environmental degradation.

42. For the rural-agricultural areas, settlements should be projected in the context, and as part, of comprehensive planning of regional settlement systems. As agricultural reconstruction progresses, the major current functions performed by the intermediate cities and smaller towns (of being service centres and trading places for the farmer's produce and the goods, implements and services he requires) need to be supplemented now by certain other functions. The technology of the recent world-wide agricultural revolution requires fewer men and more land for higher productivity. Concurrently, medical technology and sanitation tend to produce a steady growth of rural populations. Redundant rural people will therefore have to find alternative employment in increasing numbers, first, perhaps, in industries based on agriculture or industries supporting agricultural productivity, and subsequently, in building, in infrastructural development and in other industries that could be suitably based there. This suggests for certain towns the role of "growth poles", and, therefore, also the role of an alternative point of attraction for the rural-urban migration, closer to home than the metropolitan cities.

43. Certain towns located in large agricultural zones far from any metropolis meet the requirements for a real test of the concept of "agro-ville" as carriers of agricultural reconstruction and links between agricultural zones and the metropolis within city-regions. When such towns are located closer to a metropolis, their development must be planned, of course, as a component agglomeration of the regional urban system (or a city-region). Such rural zones will certainly undergo a substantial transformation. From producing staples they should move, preferably, to cultivating intensively products for immediate consumption in the metropolitan markets (such as vegetables, fruit, dairy products and meat). This transformation may imply a higher ratio of employment to land as well as higher productivity, and higher levels of income, living and general well-being than those prevailing in other agricultural areas. They may probably come much closer to the levels prevailing in industrial employment. These factors, combined with judicious investment for expansion of the physical, social and economic infrastructure in the region, may offer the needed incentives and external

economies required to deflect (at least partially) from central cities the relentless flow of rural migration and undue concentration of production.

44. In general, new production facilities tend to settle in predominantly urbanized areas near consumer markets, where there is also sufficient labour available and where requisite research, communications and other vital services already exist. Rural-urban migrants follow the same trend in the hope of improving living conditions where economic activity is occurring. As an alternative, the following objectives and policies for regional development, for settlement systems planning and deliberate urbanization have been suggested and are being implemented, at least in part:

(a) Establishing, through sufficient infrastructural investment within the wider regions of the already overcrowded metropolitan areas, suitably equipped alternative centres for industry, commerce, culture and residence so as to reduce the pressure on central cities now plagued by rural migration, by physical congestion and other social and environmental problems (examples are Tokyo and the Kinki region in Japan);

(b) Creating, through even larger infrastructural investment, adequate economic opportunities and sufficient social and cultural services in the urban and rural areas of regions as yet underdeveloped, so as to deflect the flow of migration to areas capable of productive growth (examples are Skopje, Macedonia, Yugoslavia, and Nagoya, Chubu region, Japan);

(c) Strengthening the economies and infrastructure in rural zones and smaller towns and cities, expansion of their trade and industry, betterment of living conditions through suitable environmental development, improved social, educational and health services and enlarged industrial job opportunities, so as to minimize the need for internal migration and enhance the geographical distribution of employment;

(d) Redeveloping the large metropolitan regions and reinforcing their economies by judiciously investing in capital-intensive industries and services for higher productivity as well as improving the quality of life through better environmental design and better social and cultural facilities, so as to obviate or reduce the need for further physical expansion of central cities.<sup>14</sup>

45. In implementing the objectives of national urban policies, much reliance must be placed upon the development of regional infrastructures and their performance in the interest of their larger communities. In Japan, for example, nine planning regions were established in the 1960s. Comprehensive planning of infrastructural development for these nine regions followed, thus recognizing its essential contribution as a major means for achieving regional and urban development objectives, consistently with national development planning. Unified regional infrastructural systems integrating the different modes of transportation

<sup>14</sup> "Report on the 1964 Mission on Urbanization and Regional Development" (TAO/Japan/2).

and communications, the power network and the utilities are the probable solution.

46. At the current point of development of the world's societies the setting for any further progress has shifted to the great metropolitan concentrations. These exploding urban formations are the places where the essential economic, political and social processes and problems of the world's societies come together. Their interaction is becoming increasingly counter-productive. However, mutual accommodation and adjustment could render their interplay highly productive and, thus, also more effective in terms of material wealth, delivery of services and social well-being as well as in terms of human qualities of life. The great metropolitan areas of the world demonstrate most dramatically the cumulative stresses imposed by man-made development upon nature's ability to recycle the growing concentration of industrial and other man-made wastes. But the interaction of the two environmental systems does not have to be destructive of nature and man. Technologies are known that can stop pollution at its source. The argument that their application is "uneconomic" cannot stand. What "economic value" could be put on human

survival and well-being? As a world society the United Nations possesses adequate economic and material resources and the required human capacities and skills to accomplish this task everywhere.<sup>15</sup>

<sup>15</sup>The urban and environmental crisis is a challenge to human sense and to the political sense of the community of nations. It is so vast and requires such large resources that it cannot be resolved by national planning and national and local action alone. The problem of human settlements has therefore held the attention of the United Nations from the time of its inception. It was a major topic at the United Nations Conference on the Human Environment at Stockholm, 1972, where its gravity and urgency was underscored by recommendations for: (a) a continuing programme of environmental improvement through pilot projects and demonstrations in "areas which could vary in size from city block to a national region"; and (b) a Conference/Demonstration on Experimental Human Settlements to be held under the auspices of the United Nations in order to "maintain the momentum of the United Nations Conference on the Human Environment in this area". The General Assembly approved the convening of a Conference/Exposition (on human settlements) "the preparation for which should generate a review of policies and programmes, national and international, and should result in the selection and support of a series of demonstration projects sponsored by individual countries and the United Nations". The Assembly also accepted the offer of the Government of Canada to act as host to the Conference-Exposition, at Vancouver in the spring of 1976. (General Assembly resolution 3001 (XXVII) of 15 December 1972.)

## SOME ISSUES RELATING TO POPULATION DISTRIBUTION POLICIES \*

*United Nations Secretariat\*\**

### BACKGROUND INFORMATION

1. The United Nations has been increasingly concerned with the issues and problems raised by urban growth and development over the past two decades, as cities have begun to account for increasing proportions of the world's population, thereby becoming key sectors of national economies. Beginning in the mid-1950s, emphasis was placed upon problems caused by rapid urban growth, such as community development and social welfare. Recently, emphasis has shifted from concern with specific problems to a better understanding of the process itself.

2. The United Nations, in co-operation with the Government of the United Kingdom of Great Britain and Northern Ireland, organized an Interregional Seminar on New Towns, which was held in London from 4 to 19 June 1973. The purpose of the Seminar was to identify the key factors that should be considered in formulating national urbanization policies, and to explore the possibilities of using the "new towns" concept as a tool in creating a desired pattern of urban settlements in developed and developing countries.

3. The following is a summary of issues, problems and policies discussed at the Seminar which are of direct concern to this paper. The work of consultants Lauchlin Currie, Ernest Weissmann and Kazimierz Dziejowski, and material from other United Nations publications are used to support various points raised by the consultants and seminar participants.

#### *Past and present trends*

4. The total world population may reach nearly 7 thousand million at the end of the century. By that time, about half of this number will live in urban areas. During the 1970s alone, an estimated 490 million people will need some urban space. Today, great concern is felt for the dramatic impact of high population growth rates and urbanization on the present and future conditions of human settlements in the developing countries. Rapid shifts in population distribution and growth, together with uneven distribution of economic activities, confront cities, towns and villages with a sense of

desperate urgency about urban development and priorities in national development planning.

5. In spite of the high rates of migration from rural to urban areas, the world's rural population will also continue to grow significantly, adding to the "push" of population off the land and placing further pressure on already overcrowded cities and towns. Urbanization trends in most developing countries were already resulting in the expansion of single or of a very few large cities in which the bulk of industrial and economic development had taken place. The growth of population in urban areas, however, is not only the result of the inflow of migrants from rural areas, but is further aggravated by the natural increase of the original urban population due to the high fertility rate which still exists in the developing world. In most developing countries, however, there is no frame of reference to assist Governments in deciding alternative strategies for urban development and in defining the nature and function of urbanization. The distribution of population within a country is of the greatest importance for development and can only be considered in the light of a thorough analysis of the existing situation, the ultimate aims of society, the availability of resources and the objectives of development.

#### *National development and urbanization*

6. The causes of population increase and massive migrations are well known and they are common to most countries, developed and developing alike. However, the scale and direction of these changes vary considerably among countries with different levels of socio-economic development and population densities. Although problems and policy factors are again largely common to most countries, the attitudes towards urbanization vary.

7. A recent United Nations survey on urbanization and development shows that in national development planning the relationship between urbanization and development is not fully recognized. Failure to consider urbanization as a major phenomenon influencing development has a direct bearing on policy formulation related to all aspects of urban development and has been a basic deficiency characterizing the preparation of development plans during the past decade.

"In many instances the process of urbanization and its effects on the distribution of the population has been misunderstood or ignored and, consequently, the

\* Revised version of paper (E/CONF.60/SYM.III/21) submitted to the Symposium on Population, Resources and Environment, Stockholm, 26 September-5 October 1973.

\*\* Centre for Housing, Building and Planning of the Department of Economic and Social Affairs.

analytical basis required for the formulation of coherent urbanization policies is too often distorted. The growth of slums and squatter settlements in the cities of almost all developing countries is a clear manifestation of such an attitude.”<sup>1</sup>

8. Although many sectoral national planning decisions have implicit urbanization policies, only relatively few countries eventually take urbanization into account and base their national development policies on taking advantage of such a phenomenon as a positive factor. From the beginning of the post-war period, many Governments and peoples of developing countries have acknowledged the primacy of economic development and social change. However, government agencies engaged in promoting all kinds of new enterprises, activities and investments have simply not been aware of the long-term implications of their initiatives and of their effects on urban development. And, as stated recently by a group of experts, when it became apparent that urban growth demanded serious attention, the reaction was to oppose urban expansion without acknowledging how closely it was connected to development policies sectorally formulated.<sup>2</sup>

9. In this regard, the Seminar concluded that the higher levels of urbanization that prevailed in developing countries were not only unavoidable, but might be necessary for rapid economic growth and national development.

“Urbanization should not be regarded as a negative process; it should be accepted both as a condition for, and the result of, development. Recognition and acceptance of the intrinsic interrelationships between urbanization, modernization of agriculture and overall development are essential for the setting of goals and for the formulation of policies, plans and programmes . . . The need to give high priority to improvement in agriculture, leading to increased production and the general improvement of living conditions in rural areas is obvious; it must, however, be considered in its own right and not as a means of reducing rural-urban migration.”<sup>3</sup>

Urbanization trends will not only continue but may well increase and their effects, both in terms of accommodation of the population and in providing employment opportunities in an urban environment, must be anticipated as a condition for success in any development programme.

#### *Growth and urbanization*

10. A common theme in the developing countries is a desire to increase the national well-being expressed as increasing the gross net product (GNP), and sometimes

coupled with economic and/or societal structural changes. An equally common recognition is that the increase in the levels of national well-being necessarily require changes in the sectoral composition of the national economy, in terms of both GNP component and employment. A whole school of economic thought claims that increased levels of well-being call for decreasing the proportions of the agricultural sector and augmenting the levels of urbanization that currently prevail in the developing countries.

11. The need to have a small portion of the total labour force in agriculture was stated by Lauchlin Currie to be evident both from the historical development pattern of today's developed countries and from well-established traditional Keynesian macro-economic principles.

12. Increasing the level of well-being in the developing countries requires higher levels of output in all sectors of the economy, particularly health, education, housing and food, and a more equitable distribution of income among all segments of the population. The chief point at issue, then, is whether higher output necessitates urbanization. The possibility of attaining a satisfactory rate of growth and a high level of income for a rural population, regardless of its relative size in the total population, depends upon the interplay of two basic economic concepts—productivity and elasticity of demand.

13. The advances in productivity in agriculture in developed countries have often outrun or rivalled the advances in industry. The record in the developed countries shows that the increases in agricultural productivity were the result of increasing the capital/output ratio in economic-sized plots of a commercial type. In the United States of America, 6 per cent of the labour force produces all the domestic and exported output of foodstuffs and fibres, of which 2 per cent, represented by the larger commercial farms, produce some 80 per cent of the total output. The yields obtained in experimental plots and in the commercial type of mechanized farming in Colombia are far above those obtained in the traditional farming on small plots. With the widespread use of modern farming techniques on economic-sized plots, some 14 per cent of the labour force could have produced the harvest of 1960, instead of some 45 per cent. In other words, productive potential exists in agriculture.<sup>4</sup>

14. The exploitation of that productive potential, by providing all the people in farming with economic-sized farms, obviously depends upon the availability of land. Furthermore, there is another factor that requires a relatively low level of agricultural production. Low elasticities of demand indicate a situation where consumption of agricultural goods increases proportionately less than the increase in income. As income increases, a greater proportion of it is spent on non-agricultural

products. Empirical studies demonstrate almost universally that, both in income and in price, elasticity of demand for agricultural products is very low, particularly in terms of calories or produce at the farm-gate.

15. Both the existence of productive potential in agriculture and the income elasticity of demand imply that, if high growth rates can be achieved in developing countries, an extraordinarily high rate of growth is unavoidable in places where goods with high elasticity of demand are produced—that is, in cities. Simultaneously, a very low rate of growth will be observed where agricultural goods are produced, i.e., in rural areas. In other words, equal rates of growth are incompatible with high over-all rates of growth. Stated in different terms, growth must be unequal in terms of both sectors and regions if high aggregate growth rates are desired. “This is the basic economic reason why urbanization is inextricably bound up with development.”<sup>5</sup>

#### *Structural change and urbanization*

16. Economic growth for the benefit of all strata of society is only one reason why urbanization should be seen as an essential process of national development. There is evidence that cities are or may become the sites of increasing rates of social mobility and occupational change, of higher levels of education, of better diets, health, housing etc., and of a more favourable demographic structure, particularly declining birth rates. Lastly, cities become the arenas where a previously inaccessible population can effectively voice its desires and priorities.

17. The role that urbanization and urban development play in social and economic development, and the consequent importance of the provision of a fertile environment in which social equity and economic growth can prosper, is often underestimated. The human settlements system as a whole, and each of its components individually, must provide in an orchestrated manner for:

(a) Efficiency in economic growth and increased productivity;

(b) Social promotion, greater social equity, social mobility and social intercourse;

(c) Social satisfaction which, although dependent upon economic growth and social promotion, also depends upon the quality of the environment in biological, functional and aesthetic terms:

“Urbanization should also be considered in its role of diffusing cultural and technological knowledge; such knowledge is the true agent of change in the modernization of traditional rural settlements and their economic and social life. These positive aspects of urbanization must therefore be taken into account in the formulation of national urbanization policies.”<sup>6</sup>

18. The extent to which the agricultural population will decline will vary, depending upon the diversification of the crop basis, export potential and rural land-ownership patterns. In any case, substantial reductions in the agricultural labour force (population) are to be expected. The questions then concern where and how well the increasing non-agricultural population would be accommodated.

#### *Policies concerning urbanization*

19. The Seminar's recommendations reflect a general consensus on the irreversibility of the urbanization process. In the opinion of the majority of participants, urbanization is an inevitable consequence of development and should be accepted as such. It is also an essential condition for economic and social development. However, there are countries where urbanization is still regarded as a negative process. Such views have the effect of delaying the adoption of appropriate policies. Too often, resources for urban development are being implicitly or explicitly restricted, with the expectation that, by favouring rural development, migration will be lessened and urban problems solved. The view that a forced slowing of migration from rural areas would solve the problems of urban development was contested as lacking realism. It was difficult to find any examples of this process taking place successfully, since it was not viable economically and was socially unjust.

20. For many years, urban growth policy and planning at national, regional and local levels continued to be based on piecemeal, largely negative or restrictive reactions to urban growth and concentrations, without succeeding in making any substantial impact on conditions and trends of urban expansion. Although government actions in areas such as mechanization of agriculture, promotion of large-scale imported technologies, concentration of investments in specific resource locations, infrastructure and public works investments, and credit and subsidy policies had direct bearing upon the distribution of the population and upon settlement sizes, urban development policies were largely formulated independently of governmental actions.

21. There cannot be a universally desirable pattern of population distribution between settlements of different sizes. Some degree of concentration or primacy may be unavoidable at the beginning of the process of industrialization. At the initial stages of development a certain degree of concentration is justifiable to maximize investments and speed up development, provided that profits gained from maximization are reinvested in the concentrated area and not diverted or expatriated. An excessive emphasis on dispersing migration at the earliest stages of development will require the dispersal of resources for infrastructure and services, which may not be in the direct interest of accelerated development.

22. An increasing number of the developing countries have adopted, or are beginning to formulate, national population distribution policies. These policies have derived, in part, from the increasingly pronounced

<sup>5</sup> *Ibid.*, p. 5.

<sup>6</sup> ESA/HBP/AC.9/48, p. 70.

nature of regional disparities, the acceleration and concentration of urban development, the dominance of "primate" cities, the stress syndrome in large cities, the failure to develop positive strategies on large-scale urban development and the desire to achieve the maximum output from various sectoral investments in particular areas or regions. An important characteristic of such policies is the increasing importance placed upon regionalization of national development plans. However, only a few examples are known of effective implementation of regional planning strategies.

23. At first, most regional plans were conceived essentially as instruments to deal with problems of particular regions. Regional planning has gradually become a planning strategy for regionalization of development plans, although the necessary organizational capability is still largely lacking in most countries. The regional plans are not seen as substitutes for either local or national plans, but as a strategy to enhance the efficiency of both levels.

24. Recognizing the importance and potentials of regional planning as an instrument for implementing national development goals, the Seminar recommended that development be undertaken on the basis of a comprehensive regional plan:

"While in some countries it may not be feasible, at least for the time being, to undertake regional planning in its full operative sense as an instrument for investment decisions, the strategy to be adopted should certainly be based on comprehensive regional analysis. This approach will make it possible to determine urban-rural interrelationships, to analyse the whole system of human settlement systems as the expression of social and economic development, matching the settlement of people with the creation of jobs and the provision of services. While economic development clearly requires the maximum use of all available resources, the development of regions where higher returns can be expected should initially receive priority, owing to technical limitations, capital investment shortages and lack of skilled personnel, both technical and managerial. The notion of equity in geographical terms should be regarded as a long-term objective which might have to be achieved by stages."<sup>7</sup>

#### UNDERLYING MECHANISMS RELATING TO URBANIZATION

##### *The inherited patterns*

25. The settlement pattern at any moment in history reflects the basic order of the prevailing social and economic activities in a country. The Seminar, recognizing that the distribution of population within a country is of the greatest importance for development, reaffirmed the impossibility of pin-pointing one pattern of population distribution as being the most desirable strategy to

advocate for efficient and equitable development. Among countries of the developing world, urbanization and industrialization are being experienced at various stages. Consequently, any effective policy of population distribution related to national development strategy should be formulated with a careful assessment of historical development patterns.

26. As a result of historical structural dependencies, countries with colonial histories are facing special urbanization problems today. A common characteristic of many of these countries is the existence of a poor urban network, urbanization having taken place almost exclusively in one city or in a few "primate" cities of colonial origin. The location, function and development of such cities reflect the dependency between raw material-producing countries and outside colonial Powers. Prior to independence, development investments initiated by foreign investors took place within the primate city environment with concentrated key facilities, infrastructure and job opportunities. Later, after independence, these existing trends were reinforced, opening a single avenue for the influx of both needed investments and uncontrolled rural migration. As pointed out by the Seminar, the interaction of economic development, technology, population growth, urbanization and the human condition is now globally accepted. The improvement of health and sanitation measures have brought about dramatic changes in the life expectancy of the rural population. More food is produced by fewer farmers cultivating more land, though not necessarily satisfying an increasing demand. These factors, added to the desperate search for income, have generated a relentless stream of migrants that keeps densifying an already alarming population concentration in primate cities. Yet, it is precisely this reality that should not be viewed as a negative process, but understood as a condition for, as well as the result of, development. As already mentioned, it is essential to recognize and accept the intrinsic interrelationships between urbanization, modernization of agriculture and over-all development as potential factors to help in formulating goals and policies, plans and programmes.

##### *Development and settlement pattern*

27. A network of settlements can be referred to as a "system of urban places" where mutual interdependencies exist among towns, cities and settlements of all kinds belonging to a single national entity. Each settlement within such a system hierarchy performs a function or several specific functions. National development may imply a change in the composition and aggregate level of these functions. The settlement system is not only a geographical phenomenon but, as underlined by Kazimierz Dziewonski, an historical phenomenon in time and space as well.

28. The history of settlement of a given country can be analysed as it relates to the uncontrolled or determined evolution of a nation's development and wealth. Indeed, the transformation of society can be

<sup>7</sup> *Ibid.*, p. 73.

observed through the evolution of its settlement pattern. Such a transformation takes place in time, whatever the underlying goals and strategies may be. This implies that at specific periods a coexistence of incoming and outgoing orders would always prevail. The transition from one socio-economic order to another requires a necessary and unavoidable adjustment in infrastructure. While changes in society tend to be assimilated rapidly and to supersede prevailing values, the infrastructural evolution takes place at a slower rate. The new elements of technical, economic and social infrastructure are often just added on to existing ones.

29. Urban development cannot be dissociated from deliberate changes in national culture and social consciousness. Urbanization means also a specific way of life and a distinct culture. Therefore, urbanization and population distribution policies need to be geared to manipulating key variables in these changes, rather than to concentrating on ways to alleviate the undesirable effects of the forces underlying societal transformation.

30. As a society changes from a predominantly agrarian structure to a modern industrial one, certain typical differences emerge:

(a) The process begins with a self-sufficient subsistence economy with little investment and trade. The dominant settlement is the village or local urban-rural place with a population parallel to that of the natural resources, primarily land;

(b) With improvements in transport and trade, support and service activities are carried on for the village economy by a new and growing non-farming population. The materials, the market and the labour are all furnished originally by the agricultural population. There are universal similarities in the relationships between settlements appearing in the first stage and these "central places" with regard to their relative size and location;

(c) With further improvements in transportation technology and with increasing interregional trade, a region goes through a succession of agricultural land-use intensities;

(d) Mining and manufacturing activities gain increasing importance as a result of augmented productivity and emerging consumption patterns. Improvements in technology, due to industrialization and increasing national wealth, give rise to a number of large centres of specialized services and manufacturing.

"The settlements systems in many developing countries have been initiated by exogenous forces in the period of colonial rule. They may therefore no longer correspond to the radically changed requirements and objectives of the country nor do they facilitate the achievement of development goals. In many cases, therefore, they must be consciously reshaped. Urbanization policies must be formulated, strategies selected and plans prepared and implemented to this effect."<sup>8</sup>

<sup>8</sup> *Ibid.*, p. 76.

### *Size of settlements—determinants*

31. One way to identify the settlement subsystem is to isolate urban places according to their size and the economic, social and institutional roles they play in the country's structure. Three types of spatially integrated settlements emerge. They are large urban agglomerations (metropolitan areas or conurbations), networks of regional centres and subcentres (also called subsystems of regional growth poles) and local urban-rural settlement complexes.

32. The growth of large urban agglomerations, especially in the early stages of economic development, is almost unavoidable. The economic advantages of concentration, together with rapid technological progress in the provision of communal services, lead to the creation of large concentrations of population and hence to the spatial explosion of large cities. This phenomenon has its manifestation in developing countries in the growth of primate cities, whose nature and evolution have already been analysed. The Seminar recognized the importance and role of metropolitan regions and primate cities. They are considered to be of paramount economic significance for developing countries, particularly for those experiencing the early stages of development. At such early stages of industrialization, the concentration of activities within one city could be justified from the point of view of economy of resources. Thus, there is a direct relationship between the levels of development and primacy; the less developed the country, the higher the degree of primacy.

33. Regional growth centres have several distinct functions. Large enough to be of major importance within their region, they act both as centres of progress and as administrative capitals. When a higher degree of equity becomes an essential objective of development, regional growth centres begin to play an important role by counterbalancing the one-sided growth of primate cities. Indeed, when the urgency of development combined with the scarcity of resources favours primate city development, built-in provisions should allow the planning process to divert resources and energies into the development of alternative growth centres. Failure to introduce at an appropriate time the necessary mechanisms to facilitate the growth of secondary cities or new growth poles would result in over-concentration and diseconomies of scale difficult to control later on.

34. The local urban-rural settlement complexes can be referred to as "central place" units at the lowest rank. Various localities within such complexes differ in function and specialization, which do not depend upon the cost of transportation but upon the social division of labour. Today, the size of these settlements' limits has grown considerably as a result of technological progress and modern transport. Similarly, they play a valuable role in the diffusion of technical knowledge in agriculture and in the spread of urban values and way of life. This aspect of urbanization policy cannot be ignored by planners and policy-makers for it may help channel the

growth of small towns away from their current crisis and towards more integrated regional development.

35. The growth of centres of various levels in the settlement hierarchy depends upon various policy choices and upon their effective implementation. Those choices affect not only the absolute size of the primate city, but the nature and extent of the primate city's dominance over the urban centre network. The effect of choice in key development decisions, such as in determining the type of investment and adaptation policies, has direct and important implications on the national settlement pattern. It determines how the traditional urban centres will grow or will temporarily hold excess labour forces through product improvement or capital-saving policies. Similarly, the extent to which income gaps are created or levelled between the primate city and the rest of the country remains a powerful determinant of the scale of migration into large agglomerations.

#### *Evolution of the settlement system*

36. Different types of resources, as pointed out earlier, exert various degrees of influence at different levels of socio-economic development. In a predominantly agrarian society, the fertility of soil and climatic conditions largely determine the size of settlements and their distribution. Another set of resources (minerals, energy sources, locational advantages etc.) gains relative importance in a country in transition to the industrial stage of development. Ernest Weissmann emphasized the fact that a settlement system shaped by the demands of one development stage need not be compatible with the requirements of subsequent stages of development.<sup>9</sup> The exponential rate of technological change is likely to require flexibility in planned settlement patterns.

37. The location of economic activities has largely been uncontrolled and has been based on the firms' individual choice. These individual decisions have not posed grave problems so long as their environmental impact has been either insignificant or simply ignored, and they have carried the full responsibility for costs incurred to the community. However, "social overhead projects", an important locational determinant, has been increasingly financed by central Governments. It was noted that from one third to two thirds of the total national fixed capital was in construction and construction-related activities. The scale of such allocations requires a careful assessment of the long-term interest and welfare of the community vis-à-vis the short term individual and corporate gains which are not necessarily based on payment of full costs.

38. The developing countries, the Seminar noted, had a unique advantage over the developed countries due to the fact that the basic population distribution patterns were in a state of flux, and that considerable

opportunity existed for major changes to reflect the future needs.

39. Great flexibility should be incorporated into the desired pattern of settlement networks due to rapid technological developments and social transformations. Expressing a somewhat optimistic view, Weissmann pointed out that these developments would change the priorities in the developing countries as the basic necessities were provided. Increased emphasis would be placed upon environmental qualities, amenities etc. at advanced stages of the development process. The settlement system had to be devised in such a way as to reflect these changing priorities.

#### FACTORS DISTORTING THE UNDERLYING MECHANISM

40. The previous section has presented a discussion of the underlying mechanisms that distribute the national population among the different sectors of the economy, and in settlements of varying sizes over the national territory. The discussion concentrated on factors that the Seminar singled out as the primary determinant of a desired pattern of population distribution.

41. Besides the potential conflicts between short-term and long-term requirements, other elements may distort the emergence and evolution of a desired pattern. These elements are the municipal or government pricing policies, territorial distribution of political power and cumulative causation as it relates to terms of trade between different sectors of the population.

#### *Marginal costs versus average costs*

42. In some countries, particularly in the developing world, such a large portion of the market becomes concentrated in one metropolitan area that smaller cities have difficulty growing and attracting economic activity. In terms of the balance-sheet, each new industry or economic activity could justify its location in the single metropolitan area. However, it is doubtful whether the expense in terms of social costs is properly considered.

43. Thus far, no mechanism exists for assessing added marginal costs to the additional population. Most of the more serious criticisms that can be made of life in large cities appear to focus around the intertwined problems of urban transport and the consequences of rising urban land values. The first leads not only to a high absorption of resources that might better be used for more urgent purposes, but to high unmeasured "social" costs (time, inconvenience, irritation, noise and pollution etc.). The latter leads not only to growing inequality, but to an intensification of the undesirable urban characteristics of extraordinarily high employment densities in the centre, spatial segregation by income classes and notable differences in styles of living. These disadvantages, consequences of a questionable urban spatial organization, are the result of the social malfunctioning, in terms of the criterion of ability to pay, of the price system and land-use patterns.

<sup>9</sup> Ernest Weissmann, "Settlement systems and regional development in rapidly urbanizing countries" (ESA/HBP/AC.9/5), paper submitted to the United Nations Interregional Seminar on New Towns, London, 1973.

44. If traffic problems of large cities could be solved not by devoting ever-increasing resources to meeting traffic requirements but by reducing such requirements without loss of efficiency, and if the rise in land values resulting from growth could be retained and used by the community, the basic problems of large cities would in large part be solved. The solution, however, would entail such a sharp break with the trends that have been allowed to become established in developed countries that it probably would be unacceptable politically in such countries. Whether it would be equally unacceptable in developing countries is a moot question, since no real attempt has been made in such countries to implement the solutions.

*Territorial distribution of power*

45. In no country can the existing settlement system be explained, nor can policies related to desired future settlement systems be formulated, without explicit considerations of political realities in addition to those previously stated. Political factors play a key role in devising territorial administration, in determining the location of "public overhead investments", and in a large number of factors related to individual locational decisions such as uniform or minimum wage policies, pricing or regulating public utilities, control over location permits, taxation, subsidies etc. These factors do not show a universal pattern of impeding or facilitating the natural operation of underlying forces (in relation to regional disparities, population concentration, primacy etc.), but they have a significant impact upon the pattern of population distribution.

46. The developing countries are characterized by the concentration of political and administrative power in the primate cities. New institutional arrangements are necessary to enable the public to express their desires and priorities. It has been noted that the exclusion of the public from the planning process creates difficulties in formulating goals for development and in implementing development projects:

"The setting of clear goals is much easier in coun-

tries with a higher degree of social and economic homogeneity and political stability. Developing countries still in the process of sorting out their basic values are much more prone to political changes. A high degree of polarization, which characterizes societies in the developing world, will continue to create a degree of political instability until all sectors of society are better represented in the decision-making process."<sup>10</sup>

47. The lack of communication between the policy-makers and the general public, coupled with centralized power, prevents the full exploitation of local initiative in development efforts. There was a general consensus on the importance of regionalization of development plans as a means of encouraging public participation:

"Under conditions of political instability, policies, planning and indeed development will continue to be unsatisfactorily performed. Increased access to the decision-making by all members of the community is thus essential to provide the stability needed for planning and development which requires a sustained effort along a consistent path for relatively long periods."<sup>11</sup>

48. Economic growth is and will remain a primary target in developing countries. There is, however, a growing trend towards placing more and more importance upon equity in income distribution and emphasis on the well-being of the total population. Settlement policies must incorporate changes that would result in narrowing the income gap between the modern urban cores of big cities and the rest of the country, as well as in reducing the income gap between small minorities controlling substantial proportions of national wealth and the masses of the population. These changes will have profound impacts upon the relative importance of different geographical markets and upon the aggregate national demand for different goods and services as the income elasticities for most goods and services vary with income level.

## TECHNOLOGICAL TRANSFER, POPULATION AND ENVIRONMENT\*

Joseph J. Spengler\*\*

1. This paper is an inquiry into aspects of the transfer of advanced technology—scientific, technical and social knowledge relating to production—from very advanced economies to less developed economies, together with the impact of this transfer upon the economic state of the population of the country receiving the technology. Among the issues examined are: (a) the links between demographic trends and types of technology; (b) the stage of economic development of the country and the type of technology required; (c) conditions affecting the transferability of various technologies; (d) the degree to which such transfer can augment income and ease population pressure; and (e) the degree to which environmental degradation and pollution may be prevented. It is assumed that as the demand for labour increases and employment rises, more workers master new skills and thus form additional human capital.

2. While the emphasis here is on the transfer of improved technology, it is taken for granted that technical progress, as an aggregate, includes not only importation of superior methods but their adaptation to the requirements of the country, along with indigenous development of needed technologies and improvement of all technologies in use. It is assumed that usually, though not always, a new technology is developed or imported because a concrete need for it emerges, rather than because, as is true of most improvements, it is factor-saving as such. It follows, if an improvement is made in response to a need, that attention can be directed to minimizing its adverse effects, if any, upon environment, employment and income distribution.<sup>1</sup>

### INTERCOUNTRY DIFFERENCES

3. It is essential to keep in view the fact that developing countries both resemble and differ from one

\* The original text of this paper (E/CONF.60/SYM.III/5/Rev.1) was submitted to the Symposium on Population, Resources and Environment, Stockholm, 26 September-5 October 1973.

\*\* Professor of Economics, Duke University, Durham, North Carolina, United States of America.

<sup>1</sup> Concerning the degree to which innovation is essentially a response to a "compelling" need rather than to rising factor costs, see Nathan Rosenberg, "The direction of technological change: inducement mechanism and focusing devices", *Economic Development and Cultural Change*, vol. XVIII (October 1969), pp. 1-24; and comments thereon by Y. Hayami and V. W. Ruttan, along with Rosenberg's reply, *ibid.*, vol. XXI (January 1973), pp. 352-357. See also W. D. Nordhaus, "Some skeptical thoughts on the theory of induced innovation", *Quarterly Journal of Economics*, vol. LXXXVII (May 1973), pp. 208-219.

another, and hence in their response to the inflow of particular economy-transforming and income-augmenting technologies. These countries are alike in that their infrastructure differs from that of Europe, whose economy responded to external assistance after 1948 and within three years increased its industrial output to 34 per cent above the 1940 level. Developing countries differ from one another, however, in culture, political structure, resources and so on. Accordingly, while the process of economic development, of which the transfer and adaptation of technology are parts, is universal in operation, it tends to differ by country; for it is a quasi-organic historical process, cumulative and self-reinforcing, with discoveries of new techniques arising out of social and cultural life.<sup>2</sup>

4. If, for purposes of expositive convenience, one classifies as "developing" all countries with incomes of \$600 or less *per capita*, one finds them differing greatly in size. In 1970, of the 122 countries for which the *World Bank Atlas* provides information, 78 averaged less than \$600 *per capita*. Of these, 32 had less than 5 million inhabitants and 48 had less than 10 million inhabitants. Countries with over 100 million population were China, India, Pakistan (including Bangladesh) and Indonesia; countries with roughly over 25 million population included Brazil, Burma, Egypt, Ethiopia, Iran, the Philippines, the Republic of Korea, Thailand and Turkey. Within these 14 countries lived approximately 2 thousand million people, or about four fifths of the population situated in the developing areas of the world. It should be mentioned that incomes in the area of Hong Kong and in Singapore, with populations of 4 million and 2 million respectively, currently average close to \$1,000 *per capita*, because of a complex of conditions not present in most small countries.

5. Many of these countries have similar demographic characteristics, among them being a high rate of natural increase (2.0-3.5 per cent per annum) with a relatively

<sup>2</sup> Harry G. Johnson, *Economic Policies Toward Less Developed Countries* (Washington, D.C., Brookings Institution, 1967), especially chaps. 2-3; Celso Furtado, *Obstacles to Development in Latin America* (Garden City, New York, Doubleday, 1970), Introduction; Anne P. Carter, *Structural Change in the American Economy* (Cambridge, Mass., Harvard University Press, 1970); H. B. Chenery and L. Taylor, "Development patterns: among countries and over time", *Review of Economics and Statistics*, vol. L (1968), pp. 391-416; H. B. Chenery, "Growth and structural change", *Finance and Development*, vol. VIII (September 1971), pp. 16-72; Gustav Ranis, ed., *The Gap Between Poor and Rich Nations* (New York, St. Martin's Press, 1972).

high number of inhabitants under 15 years of age and a relatively low proportion of inhabitants of working age. As a result, potential productivity *per capita* is relatively low, the educational burden is relatively high and the capacity to form human capital is limited. Moreover, population tends to press on an often slowly expanding supply of food, and the annual influx of persons of working age presses upon a short supply of employment-producing capital and effective job-makers.

6. Developing countries also differ demographically. In 1960, density varied widely from 4 to 20 persons per square kilometre in much of Africa, Melanesia, South America and South-West Asia; from 49 to 65 persons per square kilometre in the Caribbean region, in South Asia and in much of East Asia; and to 80 persons per square kilometre in the remainder of East Asia. In the developing regions, about three fourths of the population occupied about three tenths of the area; while about one fourth of the population occupied seven tenths of the area. As a result, the degree of urbanization differed notably from one country or subregion to another. Differences in density and urbanization produce differences in urban patterns and in the man-land ratio, and hence in the availability of manpower for non-agricultural activities; the result is that countries differ in capacity to absorb technologies from abroad.

7. Developing countries differ also in their capacity to assimilate foreign technologies. Mention has been made of differences in the availability of manpower, differences which are often accentuated by shortages of natural resources, poor climate and terrain, unfavourable population distribution, imbalance between the structure of demand and the factor structure, unsatisfactory transport conditions and so on.<sup>3</sup> Many of these countries are handicapped by their small size, for only a small national market can be supplied by a small population of low-income receivers, particularly when this national market consists of small local markets prevented from expanding by unsatisfactory and expensive transport. Small market size also makes for less optimistic expectations and disposition to expand activities, and may restrict the capacity of *entrepreneurs* to develop plants of minimum-cost size. "The strong positive association between plant size and market size . . . high-lights the obstacles small nations face in achieving industrial efficiency internally, with implications for the potential contributions of trade integration".<sup>4</sup> Lastly, since development of an adequate local

market for domestic manufactures is a preliminary for a country to become a successful exporter of these manufactures, the small size of its local market can handicap a small country with respect to its potential as an exporter.

8. Because countries differ in size and pattern of urbanization and because this pattern may condition the capacity of a country to adapt or generate technological improvements, and hence its growth potential, existing patterns may be in need of modification. On the one hand, output *per capita* usually is relatively high in large urban agglomerations. On the other hand, if there is only one large city in a small country, it may be described as being short of growth poles. Hence, there may be need in the short run for several cities, or for smaller ones, even though each is less conducive to growth *per capita* than a much larger one would be. Whether this is true depends upon whether the growth of aggregate and average income of a small country will be greater in the long run, given a few cities instead of one large agglomeration.<sup>5</sup>

#### SOURCES OF GROWTH

9. The following factors are responsible for low average income and output in developing countries: "(i) a low level of technical and organizing skill residing in the human factor of production; and (ii) a small quantity of the complementary factors of production, i.e., the total of land and capital".<sup>6</sup> This statement runs counter to the belief, still popular *circa* 1960, "that infusions of 'capital', if large enough, are alone sufficient to induce 'development' ", even in the absence of extensive cultural and institutional change,<sup>7</sup> and that international differences in capital and land *per capita* had largely accounted for differences in average output. Kuznets<sup>8</sup> puts the fraction of growth in *per capita* product that is imputable to the growth of capital at only between one quarter and one fifth. He further states that the remainder may be attributed to the growth of productivity. He adds, however, that the size of this balance is exaggerated, to the extent that it has not been corrected

Mishan, *The Costs of Economic Growth* (London, Staples, 1967); E. E. Hagen and Oli Hawrylyshyn, "Analysis of world income and growth, 1955-1965", *Economic Development and Cultural Change*, vol. XVIII, No. 1, part 2 (October 1969).

for non-conventional costs and for final products, which are, in fact, intermediate products. In some of the developing countries, however, what Kuznets calls "growth of productivity" is much smaller than in developed countries.<sup>9</sup>

10. Estimates of the contributions of various sources of growth operative in a number of developed countries<sup>10</sup> have been subjected to criticism based, in part, on inadequacy of supporting data.<sup>11</sup> Even so, there is agreement with respect to the great importance of current and past progress in technology.<sup>12</sup> Thus, Kuznets observes that "improvements not caused by any extra input of resources" (i.e., of man-hours and material capital *per capita*) have been responsible for the high rate of growth *per capita* in the past century. He states:

"These 'costless' improvements are connected with the tremendous increase in the stock of useful knowledge, much of it traceable to growth of science viewed as a social institution devoted to the production of new tested and hence potentially useful knowledge. This inference is supported by the connections between the rapidly growing segments of modern developed economies in their succession over time and science-oriented-and-linked technological innovations."<sup>13</sup>

11. In view of the continuing contribution of technological progress to growth of average output, it is of concern to isolate, with reference to developing countries, the sources of improvement in technology, especially smaller cumulating sources of productive knowledge and to determine "what are the factors, particularly the economic factors, in the diffusion of existing technological knowledge", among them the profit motive.<sup>14</sup> Diffusion within a developing country differs significantly, though not entirely, from diffusion within a developed country.<sup>15</sup> For this and other

reasons, among them the slowness with which economic transformation proceeds, some, but not all, economists agree with Malenbaum that in several developing countries "changes in supply of capital and labor alone nearly account for changes in output. Technical progress is impeded; its gains are in some measure lost."<sup>16</sup>

12. Augmentation of output in developing countries other than those very richly endowed (e.g., Kuwait, the Libyan Arab Republic and Saudi Arabia), depends immediately upon the introduction of modern technology appropriate to the factor structures of those countries, and ultimately upon the degree to which the labour force of those countries can be appropriately transformed so that their economies can be made hospitable to imported technology and complementary materials, and agents of production and transport can be made sufficiently available. Successful transfer of technical procedures resembles a successful transplantation of new hybrid organisms much more closely than the transportation of a building from one country to another. As A. O. Hirschman puts it:

"Implanting a project in an underdeveloped country implies (1) a decision to accept some *status quo* traits as temporarily unchangeable characteristics of the environment that will mold the project, and (2) a decision to consider others as subject to and ready for the kind of changes that are required for making a success of the project."<sup>17</sup>

Such implantation tends to be easier when population growth is not retarding the formation of capital and the creation of an environment favourable to the assimilation of appropriate technologies and projects from abroad.

#### IMPACT OF TECHNOLOGICAL PROGRESS

13. Technological progress produces two types of effects, direct and indirect, which may be viewed from the standpoint of the individual or the economy.

14. The health of inhabitants of developing countries may be improved directly by superior medical technology or indirectly by public health measures or increases in the availability of essential foods or in their richness in nutrients. While increase in life expectancy

is the most striking direct result of the introduction of improved medical technology over the past 50 years, this result is also a joint indirect product of improved nutrition and diminished morbidity. A concomitant of improved nutrition and health is an increase in potential productive power, particularly in developing countries, where the nutrition levels of many persons are not only below optimum requirements but below minimum requirements and where the threat of food deficiencies has increased.<sup>18</sup> Improvements in health-care technology, which are being developed, should reinforce other sources of improved health if they are adapted to the needs of developing countries.<sup>19</sup> Of even greater importance is the development and introduction of superior, easier to use, methods of contraception.

15. Technological progress can increase the demand for contraception in the following ways: (a) by stimulating the employment of young women and thus increasing the alternative use-value of their time; (b) by facilitating the production of goods marketable at prices that are low in relation to average income, and thereby increasing alternatives to children; (c) by increasing the variety of goods and services and thereby increasing the cost of children in terms of goods and services.

16. Technological progress can increase both the variety of available goods and services and gross (or net) national product *per capita*. An increase in the variety of goods tends to increase the derived demand for labour and other inputs as well as to increase the ease with which production of these goods (especially new types for which demand is elastic) can be financed. Through technological advances some forms of mechanization and automation can be made conducive to an increase in employment, and hence in *per capita* output. For example, when labour surplus countries or regions are located near developed countries or regions, labour-intensive assembly operations can be established in these labour surplus regions, making them complementary to the more developed countries, and thereby reducing unemployment. Lastly, there is considerable scope for "work-restructuring" and adaptation of machines and labour to one another in ways that both improve productivity *per capita* and augment employment. Such restructuring can be carried out in one country or, given international firms serving a number of countries, in a number of countries treated jointly. In the longer run, relief from unemployment in developing countries depends upon their ability and

freedom to participate in international trade, especially if they are small.<sup>20</sup>

17. Technological progress increases the output *per capita* by reducing some inputs per unit of output, thereby releasing agents of production from some uses and making them available for other uses. An example is the release of rural manpower as agricultural output per worker rises; this release that may be partially offset by an accompanying shift to urban centres and to the non-agricultural sector of functions formerly performed by agriculturalists.<sup>21</sup> If the elasticity of the direct and/or indirect substitution for other factors is high, then the ease of absorption of released manpower will be high. Even agriculture, a sector of the economy looked upon as overloaded with labour, may be enabled to absorb more labour, at least temporarily, although in the longer run the agricultural sector is a source of resources to other sectors.<sup>22</sup>

18. Economic development, a process of which technological progress is a part, permanently destroys a part of man's environment, as well as subjects it to pollution. This adverse impact is less pronounced in a developing country than in a developed country, but the countervailing power of the latter is greater, though not always capable of completely preventing or offsetting adverse effects. This question is discussed below.

19. Economic development also has tended to be accompanied by an increase in inequality at the early stages of the economic development of a country or large region.<sup>23</sup>

20. In time, as incomes rise, increased inequality is less tolerated and may lead to socio-economic instability.<sup>24</sup> Of course, if most of the inequality-increasing increments are invested in economic development, increase in inequality in consumption will be less pronounced, and the growth process will eventually result

in a decrease in income inequality. In general, whatever increases the substitutability of labour for other factors of production, and whatever increases the orientation of consumption towards labour and labour-embodied products, will also decrease inequality.

#### CONSTRAINTS ON TECHNOLOGICAL PROGRESS

21. Economic development activates latent constraints present in the physical and social environment of both developed and developing countries. Constraints present in developing countries are more difficult to surmount, however, because these countries lack the technology, instruments and disposable inputs needed to dissipate constraints. These constraints may have their origin in the size of the country or in population density,<sup>25</sup> in cultural factors or in reversals of forms of progress (e.g., escape of tsetse fly from controls, increase in vulnerability to disease of highly selected strains of cereal plants bred free of protective genes).

22. The restrictive conditions that limit the capacity of developing countries to absorb technology from abroad vary in terms of their permanence. Some are subject to correction in time (e.g., the skill structure of the labour force)<sup>26</sup> or through international exchange, whereas others may be permanent (e.g., energy-oriented modes of agriculture).<sup>27</sup> Among the conditions restricting capacity to absorb technologies, the following are illustrative:

(a) The small size of the market and hence limited access to economies of agglomeration and scale, originating in small population and area, together with a very small amount of mobilizable "savings" (e.g., in 1970, only three African and eight Asian countries and nine countries in the Western hemisphere had a gross national product of \$6 thousand million or more). While constraints due to the small size of local markets may sometimes be eased through access to foreign markets, especially in high-income, developed countries, this access may be limited through import restrictions designed by developed countries to keep out products in which developing countries acquire a comparative advantage and an ability to market such products (e.g., labour-intensive products). It is possible, of course, as Myrdal notes,<sup>28</sup> that too much emphasis may be put upon market limitations, particularly should it prove possible to reduce optimum plant size;

<sup>25</sup> On economic and political limits associated with the small size of a country, see Donald B. Keesing, "Small population as a political handicap to national development", *American Economic Review*, vol. LXI (December 1971), pp. 956-961; H. B. Chenery and L. Taylor, *loc. cit.*

(b) Unfavourable natural resource conditions, lack of transport facilities etc., which accentuate the limits of the markets confronting *entrepreneurs*;<sup>29</sup>

(c) Insufficiency of savings, especially those which facilitate investment in critical or strategic areas, and insufficiency of technical progress. For, as Kelley and Williamson show, factor augmentation and technical progress interact, and "increased savings rates foster industrialization-urbanization and thus a more rapid decline in population growth";<sup>30</sup>

(d) Shortage of skilled manpower and technical personnel to adapt and exploit technologies brought in from the outside, and lack of supervisory personnel to manage unskilled labour;<sup>31</sup>

(e) Incorrect pricing of capital, labour, foreign exchange and other inputs, due, in part, to imperfect input markets and in part to uneconomic policies. These conditions may give rise to inferior factor combinations and, hence, favour uneconomic policies bearing upon use of technology;<sup>32</sup>

(f) A high country-wide labour/capital ratio, together with: (i) inability to increase capital quickly enough, as well as appropriately skilled and job-making personnel and other complements to labour, in order to absorb the growing population of working age; and (ii) failure of the pattern of consumption to change in ways that reduce both the capital/output ratio and the capital/labour ratio. However, as Kelley and his associates indicate,<sup>33</sup> an increase in savings may be consequent upon depression of wages by population growth;

(Continued on next page)

(g) Incompatibility between the over-all capital/labour ratio and resource structure found in developing countries, on the one hand; and, on the other, the input structure called for by technology originating in developed countries and made available for transfer to developing countries;<sup>34</sup>

(h) Much of the land in developing countries destined for agriculture may not prove capable of the sort of intensive agriculture associated with heavy use of chemicals and water, or with high-yield cultivation under the aegis of the "green revolution";<sup>35</sup>

(i) The presence of a relatively large number of unemployed can make labour-saving technology less attractive unless it is foreseen that in the longer run, technological progress will increase the aggregate demand for labour;

(j) Unless they are selected very carefully, imports of knowledge and techniques from developed countries tend to be too capital-intensive, and hence too expensive for economical use in developing countries under a variety of conditions;<sup>36</sup>

(k) At the initial stage of the transformation of a traditional economy into one absorbing new technology, it is not so much the acquisition of new technical competencies that presents problems as it is the mastery of competencies relating to the co-ordination and control of activities—especially in manufacturing, as compared with agriculture—and the assurance of full and continuous operations;<sup>37</sup>

(l) There may be too little expenditure in developing countries for research and development, i.e., for the development and absorption of new technology and the assessment of its potential environmental impact. There

may also be relatively ineffective use of resources devoted to these matters, in part because intersectoral communication is inadequate and too little attention is paid to economic and related problems.<sup>38</sup>

23. Case studies of developing countries that have absorbed newer technology and overcome capital shortage may be contrasted with case studies of developing countries that have not been similarly successful. Such comparisons are much more revealing than are international comparisons of the supposed effects of differences in the absolute and relative amounts of technical personnel, and investment in research and development; they can clarify the ways in which policies can be successfully carried out. Case studies of historical Japan and the present-day Republic of Korea suggest that flexible operational policies can enable countries to overcome some of the unfavourable effects of over-all high labour capital ratios. Ranis finds, "except for continuous process industries and industries very close to the crude raw material processing stage, there in fact exists a very substantial potential for factor proportions variability" (e.g., labour-capital substitution). Not only can capital be fully used, but there is great scope for an output-increasing learning effect, as well as for changes in output mix, when a developing country is trade-oriented.<sup>39</sup> Of great importance, of course, is the introduction of technologies similar to those developed in these countries.

#### ALTERNATIVES

24. Every developing country embodies a set of conditions which, though modifiable in time, restrict its available options and the choice of means suited to the absorption of technologies from outside, the deceleration of population growth and the augmentation of average output. A major limit is the relatively high level of unemployment found in many developing countries, together with the rapid growth of the population of working age. Therefore, capacity to absorb new technology is conditioned by its compatibility with a low over-all ratio of capital to labour and output, though economic modernization and transformation can extend these limits backwards.<sup>40</sup> Alternative courses of action may be examined under two topics, modes and factor combinations.

### Alternative modes

25. There are three principal modes whereby new technologies may be brought in from abroad and assimilated: (1) international corporations; (2) import replacement; and (3) local businessmen interested in introducing superior methods in general.

26. International corporations along with small foreign investors,<sup>41</sup> may seek to exploit local raw materials (e.g., oil and other minerals) or to develop manufacturing or service-oriented activities and achieve economies of scale. In the one case, they find foreign outlets for mineral products in a raw or, if feasible, in a more refined or manufactured state; in the other case, they develop regional chains of outlets, together with local suppliers, and thereby exploit economies of scale in market-oriented services (e.g., retail merchandising) and possibly smaller scale manufacture. The international corporation is a very effective instrument because it brings in skilled personnel, together with the scarcest components; the corporation is also able to find external markets and to train citizens of the host country. The chief concern of the host country is to derive as great a benefit as possible from the activities of the foreign corporation, in terms of revenue, share in profits, training of personnel and inflow of modern technology.

27. With respect to the second mode, until recently, import substitution made possible by tariff protection was viewed as an easy way to initiate industrialization, set up infrastructure and facilitate the introduction of newer technology. In the past, of course, import substitution has been stimulated when war has cut off imports and when developing countries have had their importing power reduced by the collapse of primary-product prices. However, with the increasing complexity and capital-intensity of imported technology, import substitution has encountered constraints, especially in small countries with small markets. It has given rise to costs, direct and indirect, some of which are easily foreseeable while others become apparent only gradually; and it has, on occasion, led to the consumption of capital-intensive consumer goods. Moreover, even when successful, import substitution has been of limited effectiveness when it has run counter to forms of specialization that could result in large volume production for sale at home and abroad. It is most effective, of course, when the size of a country and the condition of its transport system assure a sufficiently large local market.<sup>42</sup>

<sup>41</sup> G. Jones, *op. cit.*, pp. 109-111; G. Ranis, ed., *op. cit.*, chaps. 12-14; R. M. Poats, *op. cit.*, pp. 55 and 64; R. Hellmann, *The Challenge to U. S. Dominance of the International Corporation*, trans. by Peter Ruof (New York, Dunellen Co., 1971); L. R. Brown, *World Without Borders* (New York, Random House, 1972), chap. 11. Disadvantages associated with such corporations are stressed by Stephen Hymer, "The multinational corporation and the law of uneven development" in J. N. Bhagwati, ed., *Economics and the World Order* (New York, Macmillan, 1972), pp. 113-141. See also a series of studies on multinational corporations in *Fortune*, vol. LXXXVIII (August 1973), pp. 52-79.

<sup>42</sup> See Harry G. Johnson, *Economic Policies Toward Less*

28. As concerns the third mode, most of the industrial activities of a developing country need to evolve in keeping with its resource and factor structures and the want-patterns of its inhabitants. While the course of this evolution will depend in some measure upon the combined effects of technical progress and savings, it should make much more employment available than would dependence upon import substitution and multinational corporations. The growth of the bicycle industry in India affords a good example. John Wall finds that a domestically oriented industry can progress and produce favourable spillover effects.<sup>43</sup>

29. Given an evolutionary approach, three sources of resource waste can be avoided. First, the tendency to use instruments and/or individuals embodying excessive amounts of investment in physical and/or human capital can be minimized.<sup>44</sup> Secondly, full use is more likely to be made of inputs of capital and technology. Thirdly, technology, education and training of individuals and input combinations can be kept flexible and, hence, closely adjusted to the current and the prospective structures of factor prices and the state of labour and capital supply.<sup>45</sup> Such flexibility should make easier the saving of resources devoted to less productive *élite* education and the use of these resources for training potential members of the labour force. Above all, such flexibility would strengthen the forces making for reduction of unemployment, underemployment and disguised unemployment.

30. With the growth process dominated by this third mode, tastes would be more likely to develop in keeping with the mode of production than with the much more capital-oriented methods of production dominant in developed countries; as a result, the disparity between incomes and wants would not become intolerably wide, as is likely when tastes such as those found in developed countries become quite prevalent and resource-wasting *élitism*, often of colonial vintage, is perpetuated. Moreover, Myrdal finds,<sup>46</sup> there is less risk of failure in a

<sup>46</sup> G. Myrdal, *op. cit.*, vol. I, part III, especially chaps. 10, 13 and 14; also pp. 12-24. On tastes etc., see H. E. Daly's essay in John Harte and Robert Solow, eds., *The Patient Earth* (New York, Holt, Reinhart, Winston, 1971); and H. C. Coombs, "Matching ecological and economic realities", *The Economic Record* (March 1972); pp. 1-17.

modern context than that which characterized the impact of Europe on Asia before the Second World War. There would also be considerable scope for small but dispersible and cumulative improvements, and for support of efforts to miniaturize optimum plant size.<sup>47</sup> Lastly, this approach should assure the agricultural sector of its growing requirement of goods and services and the expanding agricultural labour force (swelled by the land-saving and labour-absorbing "green revolution") of its non-agricultural needs; it might even make for greater agricultural variety and thus provide some protection against risks associated with single-character uniformity, which makes a plant genetically vulnerable to crop devastation.<sup>48</sup>

#### *Alternative technologies*

31. Under static conditions, and with minimal emphasis upon futurity, the preferred mode of production is that most in keeping with the resource structure of a country. With but one technology at hand, the choice is simple. For the most economical combination of factors or inputs is that at which each input is used as nearly as possible in such circumstances that its marginal contribution to the finished product coincides with the supply price of this input. Even then, employment may not be maximized if aggregate income is unevenly distributed and, as a result, consumption is unduly capital-oriented.

32. Under dynamic conditions, a wider range of technological alternatives could be available. Among the possible attributes of technologies, a few may be mentioned: (a) They may differ in terms of the ease with which they may be absorbed into a country; (b) They may differ in their favourable and unfavourable spillover (e.g., discharge of pollutants) and in the cumulativeness of these effects; (c) Some technologies are more likely than others to make for reduction of fertility, and hence to be preferable over the longer run because the combined effect of fertility reduction and output augmentation is preferable to effects produced by technologies with less contribution to fertility reduction. For example, a technology that eases the entry of women into the labour force, fosters urbanization or makes certain products attainable may discourage fertility;<sup>49</sup> (d) Some relate to the near future, whereas others are relevant only to the more distant future; (e) Technologies differ also with respect to the inputs whose relative use they increase or decrease.

<sup>47</sup> See, for example, various issues of *Small Industry Bulletin for Asia and the Far East*, and *Industrialization and Productivity Bulletin* (United Nations publications).

Brown, *Increasing World Food Output* (Washington, D.C., United States Department of Agriculture, 1965), pp. 51-61; *idem*, *Seeds of Change: The Green Revolution and Development in the Seventies* (New York, Praeger, 1970); Tom Alexander, "Ominous changes in the world's weather", *Fortune*, vol. LXXXIX (February 1974), pp. 90ff., in particular p. 152.

<sup>49</sup> J. N. Morgan, B. Strümpel and E. Zahn, eds., *Human Behavior in Economic Affairs* (San Francisco, Jossey-Bass, Inc., 1972), chaps. 12-13.

33. As a rule, the most important choice confronting a developing country is that between a capital-absorbing, labour-displacing technique and its opposite, a capital-economizing, labour-oriented technique. Capital-oriented techniques are economically justified for two reasons: that they embody much know-how and hence make for high output per worker, and they thus make possible a high rate of savings and thereby facilitate growth and the transformation of the economy.<sup>50</sup> Use of these techniques tends to limit employment and access to "learning" effects, except in so far as more and shorter period shifts of labour, and hence more workers, can be used with these techniques. Capital-oriented techniques make for unemployment by accentuating other shortages of capital encountered in developing countries—e.g., shortages occasioned by abnormally low prices for capital and by consumption patterns unduly oriented to capital-intensive products—and by absorbing higher grades of personnel complementary to unskilled labour, made less employable by a shortage of supervisory and other job-making personnel.

34. Healey's survey of development-policy literature suggests that a number of conditions make for capital-intensive modes of production when, given existing factor structures, less capital-intensive modes would make for less waste of capital and less unemployment, the volume of which is sustained and increased by high rates of population growth. Capital-intensivity has been accentuated by the importation of technology and equipment from modern labour-short, capital-long countries, as well as by the importation of ideas and policies stressing government planning and exchange control, heavy industry, import substitution and quasi-autarky, along with neglect of agriculture, as well as of growing inequality and unemployment. This capital-intensive policy is now coming to be doubted, as "signs of failure" become more obvious.<sup>51</sup> It is possible, therefore, that greater consideration will now be given to the fuller and more conservative use of scarce resources (e.g., capital), as well as to control of pollution and environmental degradation.

35. Several conclusions follow from this discussion of technological alternatives. First, more emphasis must be put on: control of fertility, given the increase of current unemployment as a result of past high fertility; labour-intensive modes of production, since some capital-intensive activity is unavoidable and elimination of unemployment is difficult, given a high labour-force growth rate and misuse of capital; production patterns oriented to the supply of products priced nearly within the reach of the mass of the working population, and hence conducive to control of family size. Secondly, institutions and organizations engaged in facilitating the

<sup>50</sup> See A. K. Sen, *Choice of Techniques* (Oxford, Blackwell, 1960), chaps. 2, 8; A. C. Kelley, J. G. Williamson and R. J. Cheetham, "Biased technological progress, . . .", *loc. cit.*; Frances Stewart, "Choice of technique in developing countries", *Journal of Development Studies*, vol. IX (October 1972), pp. 99-122.

<sup>51</sup> D. T. Healey, *loc. cit.*, pp. 772-795; S. Enke, *loc. cit.*

transfer of technology to a developing country must take into account its resource structure, its unemployment situation and its risk of environmental degradation and pollution from particular technologies.<sup>52</sup> Thirdly, adaptation of the experience of the Republic of Korea to less densely peopled countries is indicated.

#### POPULATION, TECHNOLOGY AND ENVIRONMENTAL QUALITY

36. Forms of environmental degradation may be variously categorized. For example, short-lived and essentially non-cumulative pollutants must be distinguished from those with longer life. The former category includes products of combustion (carbon monoxide, carbon dioxide, oxides of nitrogen, oxides of sulphur, hydrocarbons, and particulates) and some water pollutants. Radiation, pesticides, heavy metals and chemicals are in the latter category. These forms may also be classified in terms of their causes: (a) exploitation of the surface and subsurface of the earth in search of sources of energy (fossil fuels and fissionable material), of minerals and raw materials, and of sources of the products of agriculture, sea and forest under non-sustainable conditions; (b) accumulation and maldistribution of unused and non-utilizable residuals generated in the course of consumption or production. Forms may also be classified according to the degree to which they are connected with modern technology, rather than with population growth, as such, and hence need to be controlled through changes in technology.

37. The ultimate source of residuals, pollutants etc. is human consumption, since the demand both for exploitation of the environment and for production as such is a derived demand originating in the pattern of a population's wants as effectively expressed by the volume and character of its aggregate consumption. While this aggregate increases, *ceteris paribus*, as the number of consumers (i.e., population) and average consumption increase, its contribution to the deterioration of the environment will rise or fall with changes in the methods of production or in the composition of aggregate consumption.

38. Given sufficient increase in population, or average consumption, or both, in a given region, deterioration of environmental quality will set in. Attempts will be made to raise the level of cultivation and rate of exploitation of reproducible organic life above sustainable carrying capacities, often with the result that both aggregate output and capacity decline.<sup>53</sup> These attempts are likely to be accompanied by an increase in pollutants in the form of persistent insecticides and herbicides utilized to counteract threats to the enlarged volume of plant life. Exploitation of mineral and related resources is extended into increasingly less resource-rich re-

gions, with the result that more and more terrain has to be torn up in order to yield a given amount of resources;<sup>54</sup> in the longer run, the economically realizable output itself shrinks. Meanwhile, the aggregate flow of residuals increases, along with the average cost of disposing of them. Their adverse effects upon human health also increase. Some forms of pollution (rising acidity in rain) may also reduce local food-producing potential.

39. Environmental degradation is not a localized phenomenon, but one that might occur at points quite removed from its points of origin. Such high-income countries as Japan and the United States of America import large and increasing amounts of portable natural resources from other countries, where the extraction of these resources may shrink the long-run economic base, as well as disturb or degrade the environment. Pollutants originating in some countries may be carried by air or water to other countries.

40. Although both population growth and income growth tend to foster environmental degradation, their comparative impact is variable. If a 1 per cent rate of growth of average income  $y$  had the same effect as a 1 per cent increase in population  $p$ , one could set environmental pressure  $P$  equal to  $py$ , and the rate of growth  $P'$  of  $P$  approximately equal to  $p' + y'$ , where  $p'$  denoted the rate of growth of  $p$ , and  $y'$  that of  $y$ . However, the impact of  $y$  is conditioned by  $c$ , the composition of consumption, and by  $t$ , current technology. A value of 1.0 can be assigned to  $c$  and  $t$ , respectively, as of a base year; or, for purposes of international comparison, as of a base country. Then the relative values of the  $c$  and  $t$  of a country can rise above 1.0 or fall below 1.0 when intertemporal, international or inter-regional comparisons are made. If one writes  $P = pcty$ , and let  $P'$  approximate  $p' + y'ct$ , the effect of an increase in  $y$  relative to increase in  $p$  depends not only upon the comparative magnitude of the two rates,  $p'$  and  $y'$ , but also upon whether changes in  $c$  and  $t$  intensify or diminish the effect of an increase in  $y$ . Some students put major responsibility for increase in  $P$  and environmental degradation upon increases in  $y$  and the associated impact of change in  $ct$ ;<sup>55</sup> whereas others also stress the independent influence of population growth and its impact through growth of the output of products, demand for which is dominated by population growth.<sup>56</sup>

41. While a study done by Resources for the Future does not deal with all sources of pollution,<sup>57</sup> it does

<sup>54</sup> See, for example, National Academy of Sciences, *Resources and Man* (San Francisco, Calif., W. H. Freeman, 1969), in particular, chap. 6.

<sup>53</sup> See foot-note 35 above.

disclose connexions between population growth and environmental degradation, together with estimates of current capacity to control degradation. This study was based on input-output models and alternative assumptions. Population was assumed to grow on the basis of either two or three children per woman, while *per capita* income was assumed to grow at a high or a low rate. With respect to control of pollution it was assumed that current methods would continue, or that either a non-active or an active pollution-abatement policy would be pursued. Underlying the resulting estimates of the generation of pollutants were estimates of the use of natural resources, raw materials, soil nutrients, pest controls etc.<sup>58</sup>

42. The estimates of major concern for the present study are:

(a) Increase in average income was responsible for most of the increase in the generation and emission of pollutants;

(b) Even assuming great increases in population and income, an active abatement policy could reduce pollutants to a small fraction of the 1970 output with regard to particulates, hydrocarbons, oxides of nitrogen, biological oxygen required and suspended solids. Not much could be done with dissolved solids, however, the absolute amount of which would therefore increase greatly above the 1970 level. The cost of an active abatement policy would run about 2 per cent of the gross national product over the period from 1975 to 2000;

(c) Over a period of from 30 to 50 years "a direct attack on pollution dominates over a reduction in population or a reduction in economic growth as a strategy for obtaining a clean environment, at least in so far as the particular set of pollutants we have looked at are concerned". However, a slowdown in population and economic growth reduces the need for the "application of solutions the secondary consequences of which we may not like". In the long run, moreover, "reductions in population growth are probably more important than reductions in economic growth".<sup>59</sup> Even then, exhaustion of such resources as hydrocarbon fuels will make necessary changes in the sources and location of energy supplies.

43. Other pollution strategies are indicated. Taxes can be used to change the composition of consumption and production (by reducing private passenger motor-car size and shunting more travel to public transport). Direct controls can be imposed on the output of products with high-pollution emission coefficients. Zoning can be used to separate some pollution-generating economic activities from population centres. To these may be added implications of the finding that the incidence and distribution of pollutants are positively associated with city size and density within urban areas,<sup>60</sup> since it follows that, within limits, improvement in population distribu-

tion can reduce the incidence of pollutants and the health and other costs associated therewith. Only careful, long-run planning can minimize the incidence both of shrinking raw material supplies and of pollutants.

44. Modernization of agriculture has greatly increased the pollution potential of agriculture. It has concentrated livestock waste and thus generated a variety of pollutants, some of which enter ground water. Furthermore, fertilizer, which has replaced livestock waste as the major plant nutrient, can become an important source of pollution, as can herbicides and pesticides. While land is a partial substitute for plant nutrients and pesticides, this substitute is not available to land-short countries. Moreover, discontinuance of the use of herbicides and of pesticides, such as DDT, raises insect-control costs, reduces crop yields and increases the incidence of insect-borne disease.<sup>61</sup> Whence acceptable policies involve exchanges between some disadvantages and others.

#### INCOME LEVELS AND POLLUTION CONTROL

45. Augmentation of average income in developing countries depends upon growth of capital *per capita*, steady decline in the rate of population growth to or near the zero level and appropriate technological progress, particularly technological progress that is conducive to employment, urbanization and the acquisition of tastes favourable to family planning and decline in fertility. Both technological progress and increase in capital *per capita* tend to foster increase in environmental degradation and pollution, though not at first to a marked degree; for, given the low levels of income and technology in use in most developing countries, current levels of pollution are not high nor immediately susceptible to high incremental growth.

46. Demands in developing countries for control of pollution and the preservation of environmental quality are weak. First, as has been mentioned, pollution is strongly associated with modernization, a process with which developing countries have had little experience. Secondly, not only is the supply of pollutants low, but the demand for control of pollution is weak. The demand for control of pollution emerges as wants in the upper levels of the hierarchy of wants grow in relative importance and as rising incomes make more tolerable expenses associated with reduction of pollution through abatement programmes. Even so, with incomes as low as they are in developing countries and with the marginal utility of income as high as it is, the exchange between increments of income and decrements of pollution will not be very favourable to the control of pollution.

47. Several general principles are therefore in order. Initial emphasis must be put upon technological changes that adversely affect average income. Secondly, the costs of pollution control must be low absolutely in relation to incomes. Thirdly, it is desirable that when a tech-

<sup>58</sup> Ronald G. Ridker, "The economy, resource requirements, and pollution levels", in Ronald G. Ridker, *op. cit.*, pp. 35-57.

<sup>59</sup> *Ibid.*, pp. 50 and 56.

<sup>60</sup> *Ibid.*, chap. 9.

<sup>61</sup> *Ibid.*, pp. 195-201.

nology is being developed, attention be given to incorporating pollution controls in the technological instruments under consideration. Fourthly, while insensitivity to pollution control may be pronounced in a low-income country, there usually are sensitive points and areas which may function as bases for the initiation and spread of controls. Fifthly, because developing countries cannot bear heavy control costs and because the utility of particular sources of pollution (e.g., DDT) is very high in these countries, what is treated as an important pollutant in a developed country may not be so treated in a developing country. Anti-pollution strategy, therefore, calls for the selection of sensitive areas (for example, such areas as agriculture and fisheries, in which pollutants can retard growth of output) and the gradual development of sensitivity to environmental degradation in general.

48. Four sets of industrial activities can play a major role in the introduction of pollution-abatement methods into developing countries:

(1) International corporations can do this conveniently in conjunction with the industrial activities they establish, since they will have been forced to take action in their countries of origin or operation;

(2) Developed countries operating through international agencies or other channels can assist developing countries in avoiding the pollution that accompanies modernization of agriculture and in developing biological controls for pests;

(3) As motor vehicles constitute a major source of pollution, developing countries can insist upon importing, or developing locally, only relatively pollution-free vehicles (e.g., small motor-cars), for importers have access to a large number of foreign sources;

(4) As the production of energy, the most critical element in modern economies, will be increasingly subject to pollution-abatement rules in developed countries, these controls can be adapted to developing countries as required, on health and related grounds.

49. It is desirable that the health and other advantages of pollution control be made evident to the inhabitants of the controlling country, together with the adverse effects of pollutants upon the quality of the water supply and its impact on food sources (e.g., fisheries). It is desirable also that a country be aware of its possible dependency, both of the access of its exporters to foreign markets and of the state of its international relations, upon the degree to which its generation of pollutants is limited.

50. Before turning to the establishment and enforcement of rules designed to curb pollution, attention must be called to several precautions. First, given their cost, controls should not be introduced unless careful inquiry indicates that they are needed, that the benefits clearly outweigh the costs and that benefits accrue largely to those bearing these costs. Secondly, given the shortage of competent bureaucratic personnel, it would be economical to fall back on bureaucratic controls only if

satisfactory alternative methods are not available. Thirdly, the sequence of proposed controls must be considered, since there may result only a change in form of pollution (as when air pollution is converted into water pollution or clean-air requirements make for increase in fuel consumption, and, hence, in the total volume of motor exhaust fumes to be removed) or, as a result of current action, much more serious problems will be averted in future. Fourthly, the establishment of satisfactory environmental indexes will increase the likelihood that action will be taken only when really indicated. Fifthly, inquiry into the values underlying a population's attitudes towards nature and the quality of life and man's environment may reveal the way in which support for desirable pollution controls may be mobilized.

51. Four adaptive mechanisms, functioning individually or jointly, are available for control of the environmental degradation and the rate of consumption of utilizable components of the physical environment: the price mechanism; change in tastes; technological change; institutional change.<sup>62</sup> The most important adaptive mechanism is the first—i.e., change in price structure, due to the incidence of taxes, cost changes and demand shifts. Of much less importance is change in tastes, a condition subject to many influences, including response to prices and to changes in the exchange between current and future generations. Technological change can play an important part, as can institutional change (e.g., prohibitions, constraints).

52. As a rule, penalties, rewards and prohibitions will be employed to hold down forms of consumption and the generation and emission of pollutants. Taxation of polluters is, of course, cheaper and more effective than are rewards to non-polluters, although financial assistance may be indicated to developers of methods that reduce the generation, emission or incidence of pollutants. Since patterns of population distribution in many developing countries are still evolving, this evolving pattern should be oriented in pollution-averting directions. What may also be required is the encouragement of housing and other forms of construction that are less dependent upon air-conditioning (as are Western structures) and hence are dependent upon possible pollution-generating power production.

53. Increasing the welfare index of most, if not all, developing countries calls for increases in income and savings *per capita*, the introduction and adaptation of suitable technology already developed in other countries, in addition to locally developed cost-saving techniques, and control of population, since, at a minimum, the populations of developing countries seem destined to increase by at least 150-200 per cent above 1970 levels. Because of the critical importance of technological progress, it is desirable that there be established in most

<sup>62</sup> Michael Common and David Pearce, "Adaptive mechanisms, growth, and the environment: the case of natural resources", *Canadian Journal of Economics*, vol. VI (August 1973), pp. 289-300.

developing countries a small agency designed to work with locally situated industry, with local development institutions and with international and foreign agencies dealing with the origin, development and transfer of modern technology. Such an agency can serve as a clearing-house for old and new information, as an intermediary for local industry in need of technological help from externally situated sources, as a sensor of emerging environmental problems, and as an assembler and mobilizer of information, experience and methods relating to pollution control, together with the costs and benefits of such control. While the agency may also assemble and analyse information bearing upon the response of family planning to technological changes that affect the flow and composition of final product, it should not be directly involved in family planning and public health programmes. Its primary focus must remain facilitation of technological progress and the avoidance of economically avertable environmental deterioration.<sup>63</sup>

#### THE ROLE OF INCENTIVE

54. Even though a decision-maker's options are shaped and conditioned by his socio-economic *milieu*, the presence of incentive is essential to the initiation and pursuit of socially useful activities. Action results when the utility perceived to be associated with such action sufficiently outweighs its estimated cost. Control of family size, development and adaptation of new technology and avoidance of environmental degradation take place, therefore, when these conditions are realizable and when their realization is perceived by decision-makers as yielding advantages in excess of costs. Then adequate incentive to act is present.

55. Even though, in the aggregate, advantages greatly exceed disadvantages, appropriate action is likely only if costs and benefits are sufficiently internalized, and hence incident upon the decision-maker. For he acts in the light of his estimate of the costs anticipated to be incident upon him and of the benefits likely to accrue to him. If anticipated benefits are widely distributed, whereas expected costs are incident upon a decision-maker, he will not act unless appropriately subsidized. Similarly, if anticipated costs are widely distributed, while benefits flow to a decision-maker, he will act adversely to community interests, even though in the aggregate, the current and future costs of this action greatly exceed the benefits to which it gives rise; hence, the action in question needs to be prohibited, unless the gap between social costs and returns is negligible.

56. By way of illustration, consider problems associated with developing technology domestically, or adapting technology originating in a developed country,

<sup>63</sup> A number of issues tangential to this paper have been treated in H. E. Daly, ed., *Toward a Steady-State Economy* (San Francisco, Freeman and Co., 1973); see also *Daedalus*, Fall, 1973, devoted to "The no-growth society".

and hence economically costly or likely to make the importing country too dependent upon external sources.<sup>64</sup> While mechanisms underlying the development of sophisticated technology often are of limited applicability to the technological needs of a developing country,<sup>65</sup> these countries often can facilitate the flow of information concerning the implementation of domestically useful technological options,<sup>66</sup> particularly because it is "explicit recognition of an important need" that often leads to technological solutions based on science already available.<sup>67</sup> Furthermore, keys to the solution of many problems, agricultural and otherwise, are readily available in foreign publications to which Governments can facilitate access, especially when problems and needs arise. Such action may generate an environment of innovation-oriented incentive, as well as close co-operation between industry and university scientists.

57. Agriculture presents similar problems of importance because a quantitatively and qualitatively adequate supply of food and nutrients is essential to the prevention of malnutrition, so unfavourable to health and productivity,<sup>68</sup> as well as to the control of inflation; and often quite unfavourable to economic development.<sup>69</sup> Modernization of agriculture, the key to the adequacy of nutrients, is contingent upon active support by the public sector, as the rewards of private investment in agricultural progress may not be sufficiently internalized to give maximum impetus to such progress<sup>70</sup> or to prevent fertility-destroying over-cultivation<sup>71</sup> and other environment-degrading activities that in the long run can reduce agricultural capacity.

58. Mobilizing incentive to avert environmental degradation becomes more difficult when internal obstacles are accentuated by international relations. An example is preservation of the quality of coastal or offshore waters; these comprise about 8 per cent of the surface area of the world's oceans and condition the food- and recreation-supplying capacity of coastal

areas.<sup>72</sup> As a result, joint action by contiguous countries, as well as action by individual countries, often is indicated.

59. Interpretation of the impact of technological change presents difficult problems. For curbs upon technological change, although designed to prevent adverse environmental effects, can reduce incentives to potentially useful technological change at both the innovator

and the inventor levels.<sup>73</sup> Achievement of balance between these two opposed effects may be facilitated, however, by distinguishing irreversible effects from those which are reversible—a distinction sometimes difficult to make since longer run effects of given technical changes may not be easy to anticipate.<sup>74</sup>

## RESOURCES, ENVIRONMENT AND THE RATIONALE OF POPULATION POLICY \*

*Mogens Boserup* \*\*

1. The first section of this paper deals with the very general but crucial problem of whether decisions on long-term quantitative population policy could or should be influenced (or even determined) by environmental considerations and by availability of natural resources.

2. At a lower level of generality, there are a number of important interrelationships between resource availability and environment, on the one hand, and population trends, on the other. These questions are briefly considered in the second section.

3. Lastly, in the third section the concept and measurement of exhaustible resources are examined.

### THE DANGER OF REDUNDANT ARGUMENTS FOR POPULATION POLICY

4. To begin, one may ask what is the principle, or main line of reasoning, upon which a decision on the limitation of population growth can be rationally based. This topic can be further specified as two questions, by which the resources-population issue is approached from slightly different points of view:

(a) The question of the extent to which relative abundance of natural resources (agricultural land, mineral and fuel deposits etc.) can be regarded as a sufficient argument for not bothering about reduction of fertility in countries where rates of population growth are now high;

(b) The question of the extent to which scarcity (actual or expected) of natural resources is a necessary (effective) part of the motivation for adopting a long-term population policy designed to achieve the reduction of rates of population growth.

5. As soon as one begins to discuss these matters, it is immediately apparent that there are widely diverging expert opinions concerning the long-term prospects for sufficiency or depletion of natural resources for material production (energy, raw materials, food etc.). Indeed, expert opinions range all the way from extreme optimism to extreme pessimism.

6. However, this wide divergence of views need not necessarily prevent an articulate debate on the rationale

of policies for the limitation of population growth, for it is, perhaps, pertinent to ask whether this question of depletion (real or alleged) of natural resources is at all relevant for the discussion of whether there is a valid case for a policy of limitation of fertility in countries where the growth rate of population is high.

### *The doubtful relevancy of resources*

7. Clarity on this preliminary question is crucially important. In the author's view, the answer to the questions just formulated must be in the negative: even the most optimistic assessment of the prospective supply of natural resources and of new technological breakthroughs cannot lead to the conclusion that there is no need for a policy, to begin now, concerning limitation of fertility. In other words, the need for a long-term quantitative population policy is only slightly less urgent in countries with no resource problems than in countries where grave resource problems are thought to exist. Three interconnected arguments for this view are set forth below.

8. First, once the question of natural resources is set aside, one is led to consider one particular "resource", the prospective long-run supply of which points towards scarcity, without any possible doubt and controversy. This "resource", which is inexorably limited in the longer run, is, of course, mere space for human social life in decent, peaceful and civilized forms. Only in this sense is it undoubtedly true to say that humanity is placed in "a finite world", as the saying goes.

9. Secondly, however, objections will be raised that the argument given above is not universally valid. In sparsely populated countries, with relatively abundant natural resources, the "mere space" limitation just mentioned is often brushed aside as a postponable problem, i.e., as an insufficient argument for the urgency of a quantitative population policy.

10. To this answer, the appropriate rejoinder is that to postpone dealing with the problem could be warranted only where one additional condition is fulfilled, namely, that the rate of population growth in the country or region concerned is already at a comparatively low level (say, less than 1.5 per cent per annum). In countries where population growth has for many years been at a high level—say, 2 per cent per annum and above, i.e., doubling periods of 35 years or below—population dynamics is imbued with considerable inertia, that is to

\* The original text of this paper (E/CONF.60/SYM.III/14/Rev.1) was submitted to the Symposium on Population, Resources and Environment, Stockholm, 26 September-5 October 1973.

\*\* Professor of Economics, University of Copenhagen, Denmark.

say, the "braking distance" for slowing down the rate of growth is so long that it may be wise to begin to apply the brake now, in order to avoid drastic and painful measures in future, when the threat of overcrowding begins to appear. As is well known, the painfulness of fertility control coming "too late" is not only that the measures themselves might have to be all the more stringent, but that a sharp decline of fertility, suddenly imposed, necessarily gives rise to large and undesirable swings in age distribution.<sup>1</sup>

11. This reasoning might be controverted by the suggestion that in the next few decades, with some increase in *per capita* income and in the degree of urbanization, and perhaps with striking progress in the techniques of mass communication, a conspicuous decline of fertility can be firmly expected, even in the absence of any official policy favouring the limitation of the number of births.

12. At this point, the dispute is likely to end in some disagreement with respect to whether it is safe—or far too bold—to rely so heavily on the expectation that a mechanism linking economic growth and human fertility will not only work (which is plausible), but will do so in a fairly swift and smooth way, without any appreciable time lag.

13. Thirdly, it is important to distinguish between the concept of a permissible rate of increase of population, on the one hand, and the ideas, as they exist at any particular time, of the size or density of population which, given time, might "finally" be acceptable in a given country. The point is, of course, that even if the country in question is currently very thinly populated in relation to what is thought to be its potential resources, a high rate of increase may place an excessive burden on the economy in the form of "demographic investments" (machinery, dwellings, schools etc.) required to keep *per capita* equipment with capital unchanged. Thus, there are undoubtedly areas which, by any possible definition, appear to be underpopulated, so that a doubling or trebling of the current population would be regarded as not only inevitable, but desirable. This does not imply, however, that at the same time, a case does not exist for beginning to reduce the rate of population growth in these areas to manageable levels, say from 1 to 1.5 per cent per annum. The point can be put more simply by saying that there is no danger—given current rates of fertility—that an active population policy begun now would soon bring rates of population growth down to undesirably low levels.

14. While the distinction between a permissible rate of growth and a supportable final size of population is important for clear discussion, it must be stressed, at the same time, that the concept of a "limiting population size" is highly elusive and scarcely lends itself to meaningful quantification. Such quantification would require unobtainable information about both techno-

logical and sociological developments in future. To make matters more difficult, these two types of change are interdependent, since the size of population that is "sociologically supportable" depends upon the economic feasibility (determined by technological innovations) of spreading the population more evenly over the territory.

15. Still less can any meaningful statement be made about the total number at which the world population will eventually have to be stabilized, whether it is, say, 10, 20 or 30 thousand million. However, while the meaninglessness of such figures cannot be stressed too strongly, it is also important to realize that such quantification is by no means a necessary prerequisite of firm and rational decisions to be taken now with respect to quantitative, long-term population policies in those large parts of the world where rates of population growth are high. This is so because of the long "braking distance" previously mentioned, which means that it is desirable, in any event, that rates of fertility should be reduced to manageable levels as soon as possible. If this goal is achieved, it can be left, and indeed it must be left, for a future time—when the rate of population growth has been considerably reduced—to judge whether, and with what degree of urgency, further reduction of fertility towards replacement levels is desirable.

#### *Four types of countries*

16. The foregoing discussion may be further clarified by comparing and contrasting some important countries or groups of countries with markedly different demographic patterns. In order to construct an extremely simple  $2 \times 2$  matrix, a distinction may be made, on the one hand, between countries with high and low rates of population growth, to be named "Fertilia" and "Sterilia". The other distinction made is between high and low population density, characterized by the adjectives "densa" and "sparsa".<sup>2</sup> Thus, there are four characteristic groups of countries, and it would appear that most countries can, without too much oversimplifying be allocated to one of these four groups. At the same time, this grouping points out those circumstances which are likely to influence the view of Governments with respect to the desirability and the relative urgency of embarking on an active, long-term quantitative population policy. (See table below.)

17. First, ignoring the distinction by degree of density, it is to be observed that only developing countries are to be found in the two upper boxes—Fertilia densa and Fertilia sparsa. Conversely, only developed countries can be placed in the two lower boxes, Sterilia densa and Sterilia sparsa. Indeed, in most recent years, in particular since 1972, with spectacular declines of the number of births in the Federal Republic of Germany, the Netherlands, the United Kingdom and the United States of America, to name only four par-

<sup>1</sup> J. Bourgeois-Pichat and S. A. Taleb, "Un taux d'accroissement nul pour les pays en voie de développement en l'an 2000. Rêve ou réalité", *Population* (Paris), September-October 1970.

<sup>2</sup> The latinizing terminology is borrowed from an article by J. E. Meade, "Population explosion, the standard of living and social conflict", *Economic Journal*, vol. 77 (June 1967), pp. 233-255.

Growth rate of population	Population density	
	High	Low
High	<i>Fertilia densa</i> Indian subcontinent Java	<i>Fertilia sparsa</i> Continental Latin America Africa south of the Sahara
Low	<i>Sterilia densa</i> Belgium Federal Republic of Germany Japan Luxembourg Netherlands United Kingdom	<i>Sterilia sparsa</i> Northern Europe Union of Soviet Socialist Republics United States of America

ticularly important examples, it has become even truer than it formerly was that the world is split into two sharply distinguished groups, those which are developed and have low or very low rates of population growth, and those with low income and high rates of population growth.

18. Now, contrasting the two upper boxes in the matrix, the question to consider is the extent to which, in what sense and at what risk it can be said that the continuation of high rates of population growth (say, above 2 per cent per annum) is unproblematical—or even desirable—in a country of the type here designated as “*Fertilia sparsa*”, i.e., a relatively resource-rich and “empty” country. For example, one might think of Brazil, with a growth rate considerably higher than that of India and a population density comparable to that of the Union of Soviet Socialist Republics.

19. Next, consider the contrast between the two lower boxes, i.e., densely populated Western European countries where population growth rates have been low, and are currently extremely low, and, on the other hand, sparsely populated countries with a modern pattern of fertility. This comparison draws attention to the fact that in some countries, the density of population has already reached a level where it may seem desirable, chiefly for reasons of sheer space, to maintain the current low levels of population growth either by natural means or by way of immigration, or even attempt further reductions.

20. Lastly, consider the contrast, within the group of low-density countries, between those with high and those with low rates of population growth, say, Brazil as contrasted with the Soviet Union. This comparison suggests—what is perhaps the upshot of this schematic overview—that only for those countries where current density and current growth rates are both low could it be plausibly said that there is no strong case for a purely quantitative, long-term population policy.

21. This one group of countries—“*Sterilia sparsa*”—is in the lower right-hand corner of the matrix. It would seem that, even when account is taken of the recent drastic declines in births, there are only four

areas that clearly belong in this group, namely, North America, the USSR, Northern Europe, and, perhaps, some Eastern European countries.

22. To sum up, the main point of the argument developed above is that a rational discussion for and against a long-term quantitative population policy does not depend in any important way upon the view one takes of prospective scarcity or abundance of natural resources. As far as carrying capacity is concerned, the certain limitation for the human species, and, therefore, the true rationale of quantitative population policy, is not to be sought in the production possibilities—for raw materials, energy etc., but in the possibility of viable social patterns under very high population density per unit of area. With respect to the rate of population growth at any particular time, a limit is imposed, of course, by the community’s capacity to organize and finance investments.

#### *Environment and population policy*

23. Thus far, the question of resources in relation to the broad issue of long-term quantitative population policies has been considered. Turning now to the other key word in the title of this Symposium, “environment”, it must first be decided what this word stands for in the present context.

24. The problem is whether the term “human environment” is here to be taken as the sum total of all those conditions which determine the carrying capacity of a given territory. In that case, it is more or less equivalent to the concept of “space for civilized social existence of human beings”, as used above, and nothing then needs to be added here.

25. But if the word “environment”, as used in connexion with this Symposium, is meant to be more or less synonymous with “pollution” (in the broad sense of “degradation”), the question arises whether considerations of environment (in the sense just mentioned) should enter as necessary elements in a discussion of long-term quantitative population policy. In other words, one may ask whether opinions about the extent of pollution and related problems, and about the cost

of pollution control, could make any difference in a rational discussion for and against long-term population policies.

26. The answer to this question must be in the negative. Opinions on the economic dimensions of the pollution problem diverge as widely as do opinions on resource sufficiency. At one end of the scale are experts who are of the opinion that pollution control (even in a wide sense) is an important, but perfectly manageable, economic problem, perhaps a matter of 2-3 per cent of gross national product for a number of years, and far less thereafter. At the other end of the scale are, to take a drastic example, the assumptions in the Club of Rome book, *The Limits to Growth*.<sup>3</sup> This is not the place to discuss the correctness of these views, for the point is that whether one adopts one or the other of these extreme views—or an intermediate view—one's judgement about the necessity of population control in countries where rates of population growth are currently high must be exactly the same, provided the discussion is conducted in rational terms.

#### *The need for "Occam's razor"*

27. In a way, the preceding reflections are a quest for the use of "Occam's razor". This rule says that if a conclusion (for instance, that population growth rates need to be reduced where they are high) can be reached without assuming this or that hypothesis (for instance, that minerals are going to be very scarce), then there is no ground for assuming that hypothesis.

28. This golden rule is recalled not just for the sake of orderly discourse, but because there is, in the present context, a grave danger in redundant arguments. If the case for an active population policy, the objective of which is the reduction of fertility levels, is supported by inessential or redundant arguments, such as the danger of resource depletion or the dangers of pollution, one risks, in the longer run, seeing the well-known effect of crying "wolf". If, in a not-so-distant future, the view will have gained wide acceptance that the danger of resource depletion, as currently understood, is remote, the risk is that a more relaxed perception of the resources problem could then become the pretext for a relaxation of efforts for the control of population growth, because what was—mistakenly—supposed to be a major cause for misgivings on population growth will appear to have vanished. Similarly, if the pollution issue is used as an argument to persuade people of the need to control population growth, the danger is that the spread, at a later stage, of less dismal views on the costs and potentialities of pollution control might give room for unwarranted complacency in matters of population control.

<sup>3</sup> Donella H. Meadows and others, *The Limits to Growth: A Report for the Club of Rome's Project on the Predicament of Mankind* (New York: Universe Books, 1972).

## CONNEXIONS BETWEEN POPULATION, RESOURCES AND ENVIRONMENT

29. In a first and quite schematic approach a simple question may be asked concerning the main causal links between trends in the three fields of population growth, deterioration of environment and resource depletion.<sup>4</sup> One may ask about the ways in which trends in one field may be expected to reinforce (or weaken) the trend in another field, thus worsening (or mitigating) the problem within the other field.

30. Among three entities there are, of course, six possible bilateral flows from cause to effect. Three of these, indicated by broken arrows in the figure, can be safely omitted. The effects of environmental trends and of resource depletion upon the rate of population growth (the arrows "D" and "E") are major features in some apocalyptic views of future trends, to be found, for instance, in *The Limits to Growth*.<sup>5</sup> This seems far-fetched, although some special connexions may conceivably exist, for example, the as yet unproven possibility that carbon monoxide from motor-car exhausts might explain the higher frequency of heart attacks. The causation link from environment to resource depletion (arrow "F") is ignored because it seems to be an unfruitful approach. It is more pertinent to say that environmental degradation (pollution) can sometimes be regarded as being (rather than causing) a kind of resource destruction, just as anti-pollution measures may be a way of salvaging resources (e.g., recycling).

Possible bilateral flows from cause to effect

31. Thus, three of the six possible causal connexions seem to be worth considering. They are indicated by solid lines in the figure and are discussed, with extreme brevity, in the remaining part of this section.

#### *Effects of population growth on environmental degradation*<sup>6</sup>

32. As already mentioned, the pollution danger is not an effective (necessary) argument in favour of long-term population control. Admittedly, there is some

<sup>4</sup> Note that the discussion concerns the depletion of exhaustible resources. Not considered are the problems of resources which, although limited, are, under proper management, inexhaustible, for instance, agricultural land.

<sup>5</sup> Donella H. Meadows and others, *op. cit.*

<sup>6</sup> Here and in the following discussion "environmental degradation" is taken as broadly synonymous with "pollution in a wide sense".

truth in the view that the amount of pollution, and other environmental deterioration, increases with population increase, but this danger can easily be exaggerated. Far more than by the sheer increase in human numbers, current levels of pollution are caused by the growth of *per capita* income, and by the particular way in which increasing income is spent (industrialization, especially chemicals and motorization). This point can be illustrated by the figures following showing total increases over the 20 years from 1950 to 1970 in the industrialized free-enterprise countries:

	<i>Index 1970 (1950=100)</i>
Population .....	124
Gross national product in real terms .....	135
Volume of industrial production .....	173
Chemical industry .....	522
Number of motor-cars (United States of America) ..	105
Number of motor-cars (other countries) .....	820

33. In short, even if population growth were to cease altogether (not a fanciful hypothesis for the industrialized part of the world, where the pollution problem is chiefly located), pollution and other environmental problems would not appear as less important and less urgent than they currently are.

34. Turning to the developing countries, the environmental problem presents itself in a different way, which makes it more difficult (but perhaps, also, less imperative) to take full account of environmental aspects in framing policies which influence the territorial distribution of economic activity and of people in a growing population. The problems that arise in most developing countries are related to regional disparities and to the persistently strong trends towards migration from the countryside to towns.

35. Concerning regional disparities, some planners maintain that it is often too costly to attempt to distribute development activity widely over the territory. The problem reduces itself to the question of under-utilization of infrastructure. Concentration of economic development at "growing points" may be economically indicated for an initial period, which may be quite long, and it is unlikely that environmental considerations could, with good reason, often dictate another policy. This whole issue of spread *versus* concentration of development efforts is far from having been settled.

36. The net flow of people from the countryside to towns, and especially to large cities, is a universal tendency of the current time throughout the developing world, in Asia, Africa and Latin America. This trend is probably to be explained primarily as a response, both sociological and economic, to improved communications, and it gives rise to a number of important problems of economic and social policy which are beyond the scope of this article.

#### *Effects of resource use on environment*

37. It is often assumed, rather thoughtlessly, that depletion and pollution are two disasters which always

proceed together, depletion reinforcing pollution. On the contrary, it is worth pointing out that it is the other way around in the case of oil and natural gas, the sole cases of prospective scarcity or exhaustion, which is both important and improbable. For, assuming that the alternative sources of energy do materialize (so that the substitution of coal for dwindling supplies of oil and gas can be avoided), one would, by the same token, avoid the air-pollution effect of burning these fossil fuels.

#### *Effects of population growth on resource depletion*

38. This issue is highly controversial. For instance, if one asks how long the mineral resources of the earth can last, answers range from "a few decades" to the statement that mineral resources can last at least as long as mankind has any chance of lasting, in other words, that these "exhaustible" resources are practically inexhaustible *sub specie humana* (as distinct from the "cosmic" prospective).

39. Perhaps, then, the problem of resource depletion should be viewed as depending more importantly upon the rates of economic growth than upon population growth. But this latter view is also controversial, for is it not equally true that economic growth as such tends to "create" resources, and, indeed, that the amount of natural resources, rationally estimated, has in recent decades been increasing by leaps and bounds. It is interesting, incidentally, that the feat of depletion of resources arises precisely at a time when, in view of technological breakthroughs, such fears would appear to be less warranted than at any other time since man began to worry, some 200 years ago, about the sufficiency of natural resources.

40. Indeed, the very concept of resource depletion needs scrutiny, which is attempted in the following section.

#### THE SPECIAL PROBLEM OF EXHAUSTIBLE RESOURCES: DEPLETION OR GROWTH OF RESOURCES

##### *The elusive concept of exhaustible resources*

41. The very idea of "exhaustible resources" immediately suggests the question of the rhythm of exhaustion. The question may be asked if there are general and rational rules by which it can be determined at what rate exhaustible resources will be exhausted, or ought to be exhausted, given some specified political goals.

42. In order to see clearly the essence of the problem, only natural resources for material production which are exhaustible, or believed to be so, are considered. Thus, such scarce resources as natural scenery, opportunities to be alone etc., are not considered.

43. Quite arbitrarily, one may take copper ore as a typical example. It is thought of as existing in a considerable number of deposits, whether exploited or not, which are owned and run by private firms in active competition. Further, suppose that every firm has a realistic idea of the amount and quality of the copper

ore in the deposits it controls. Lastly, suppose that all of the ore is equally accessible, so that a firm's cost of extraction can be taken as independent of the amount of copper ore that has been extracted throughout the past lifetime of the mine.

44. Now, there is an old and well-known textbook rule to answer the question of how a mining firm would spread its total extraction from the mine over time, i.e., the tempo of exhaustion. The rule is simple in itself, but it becomes highly problematical when confronted with realities, as will be seen.

45. The rule says that the firm will "stretch" the production over future years in such a way that total net income throughout the lifetime of the mine, discounted to current value, will be maximized. This condition will be fulfilled, of course, when the rate of output of all copper mines taken together is at such a level that the expected future annual percentage increase in net proceeds per ton (owing to increasing scarcity) equals the interest rate with which the company has to reckon.

46. The rule is obvious once it is realized that there is a loss of interest involved in leaving the ore unmined, as "dead capital". Thus, the higher the rate of interest, i.e., the heavier the discounting of future income, the less "conservation minded" the firm will appear to be.

47. For a mining firm enjoying a more or less complete monopoly position, the same reasoning would apply, except that a monopolistic mine owner would have the added incentive for restriction of current output, thereby enabling him to raise the current price. Thus, its production policy might be expected to be somewhat more conservation-minded than that of an enterprise fully exposed to competition.

48. So far, the "pure theory" of exhaustion of exhaustible resources has been discussed. The trouble is, however, that there is nothing in real life that corresponds to it. According to the theory, mining firms, whether under competition or monopoly, would see their interest in a kind of conservation policy, limiting their current output to a level lower than that which would give the highest current profit. But the simple fact seems to be that in real life, as far as actual experience goes, private owners of exhaustible resources have tried to pursue an output policy designed to maximize current profits.<sup>7</sup>

49. This apparent contradiction between theory and reality is understandable, once the assumptions of the theory are further specified.

50. The conclusion that the owner of the exhaustible resource will economize on output (and the more so, the lower the rate of interest) is based upon the dual assumption that: (a) the producer expects increasing scarcity and, therefore, increasing net proceeds for the product in future years, and (b) he assumes that one additional ton produced today necessarily involves a

corresponding limitation on the amount of copper ore he will be able to produce in future years. But this assumption (that more production today must mean less production tomorrow) implies not only that the amount of copper ore in any particular deposit is, in fact, limited (so that the mine can be exhausted), but that the producer considers it certain (or at least probable) that the deposits will, in fact, eventually be exhausted.<sup>8</sup>

51. It is this latter assumption that does not appear to be valid in the light of the actual behaviour of owners of exhaustible resources, be they competitors or monopolists. They appear to act as if the exhaustion of the "exhaustible" resource were a rather unlikely event, or at least an event in a future so remote that a restrained production policy, far from securing maximum profit over the lifetime of the resource, entails the danger of missing a profit by not taking it home now.<sup>9</sup>

52. It is highly significant that in 1931, when the theory of exhaustible resources was first spelt out in an important article by Harold Hotelling,<sup>10</sup> it was only mentioned parenthetically, as something that might conceivably happen, that a resource, which at a certain time was regarded as exhaustible, would, in fact, as time went on, become less scarce.<sup>11</sup> Today, one would be more inclined to make the opposite assumption, namely, that many of the resources that are regarded as exhaustible and limited will, in fact, never become exhausted, because it will not be economical to continue production, in the light of future technology and increasing knowledge of other and cheaper resources, which can serve the same purpose in production.

53. Thus, over the past 40 years a major change has occurred in the economic theory of exhaustible resources. The new technical dynamics should profoundly change the ideas about kinds and quantities of natural resources, and make people realize that the amount of "exhaustible" natural resources for production, when counted in the rational way, has, in fact, been increasing by leaps and bounds, and is likely to continue to increase for quite a long time.

54. This contention about an increasing volume of resources seems shocking, and even somewhat blasphemous, to many people of good will who are fearful that mankind is rapidly wasting nature's gifts. Some further elucidation may, therefore, be warranted.

#### *Measuring the amount of natural resources*

55. Even in terms of purely physical units, the measurement of natural resources is intricate.

56. Continuing with the example of copper ore, one may ask how much of it there is. First, one must decide whether only firmly proved reserves are to count, or

<sup>7</sup> Richard L. Gordon, "A reinterpretation of the pure theory of exhaustion", *Journal of Political Economy*, vol. 75 (June 1967), pp. 274-86.

<sup>8</sup> *Ibid.*, p. 275.

<sup>9</sup> Fear of expropriation might further raise the rate of extraction.

<sup>10</sup> Harold Hotelling, "The economics of exhaustible resources", *Journal of Political Economy*, vol. 39 (April 1931), pp. 137-175.

<sup>11</sup> *Ibid.*, pp. 153 ff. and 159.

whether assumed, probable or even possible reserves should be added, perhaps with some appropriate reduction. The decision is, obviously, a rather subjective one.

57. Next, there is the problem of quality, which, perhaps, is less difficult so long as the goal is only a purely physical inventory. With mineral deposits, at least, it is often possible to estimate the degree of concentration at various depths, so that, in principle at least, the calculation in terms of some standard measure (ton of pure copper etc.) should be possible.

58. But a measurement in physically defined units is quite unsatisfactory. One wants to take the economic dimension into account, and thus one must decide what is "usable" and what is not, and for that decision everything depends upon time (the techniques available) and place (transport costs, with varying techniques). Thus, the "quantities" (in any relevant sense) of exhaustible resources change over time, not only because of extraction and use of existing quantities, but because, with the passing of time, technological innovation changes the notion of what the resources are.

59. Hence, one cannot even begin to talk about the existing quantity of a given exhaustible resource at a given time without explicit or implicit assumptions about techniques. And it is not enough in modern times—as it may have been in earlier times—to assume "technology as now known", for it is certain that technology will not remain unchanged. New possibilities continually arise for using a given natural product—or for doing without it—in part because of a reduction of raw material input for a unit of final product, and in part because of the use of substitutes.

60. Thus, the quantities of natural resources can increase. The ways in which this happens may be roughly grouped under three headings: known deposits; discovery of hitherto unknown (or only suspected) deposits; and new kinds of natural resources.

#### *Known deposits*

61. The known deposits increase, in the economic sense, when technical innovation makes it worth while to exploit them more intensively and to begin extraction from deposits hitherto known, but considered uneconomic. Improvement in transportation is particularly important in making remote deposits profitable.

#### *Unknown deposits*

62. With regard to discovery of hitherto unknown, or only suspected, deposits, an important distinction is to made here between discoveries that are the fruit of specific efforts to find more of a particular kind of resource, and, on the other hand, the general progress of geological prospecting and mapping, which proceeds more or less continuously, though at very different speeds in various countries.

63. Prospecting for oil and natural gas is typical of the first type of discovery, and it is of particular interest because this costly drilling activity is undertaken only

with a view to production needs foreseen for a fairly short period ahead. Indeed, reserves are "discovered" as the need for them arises; they are "produced", as it were. This explains why, since the 1930s, "known oil resources" have continually constituted from 20 to 30 years of consumption.

64. The kinds of resource increase mentioned above under (1) and (2) are well known and even trivial. What is new is the unprecedentedly rapid rate at which the quantities of already known kinds of resources have been increasing.

#### *New kinds of natural resources*

65. The third form of increase, new kinds of natural resources, is not trivial. Throughout the history of civilization, it has happened that materials and other phenomena in nature, which had hitherto been regarded as not being useful for the satisfaction of human needs, became "resources" owing to scientific and technological progress. What is new in recent decades is that this transformation of useless matter into valuable resources has been happening at a rate undreamed of by the most boisterous optimist.

66. A few conspicuous examples may be mentioned. Until 1942, the only practical use of uranium was to give a yellow tone to glass and porcelain. Other possibilities for the future are: common rock as the basis for extraction of metals (given sufficient energy); the mineral riches of the sea-bed; and, as concerns energy, the hundredfold increase of the "quantity" of uranium by way of the fast-breeder reactor and fusion energy from common sea water.

67. These indications sufficiently illustrate the contention that the "amount of natural resources", if calculated in a rational way, must have been increasing rapidly in recent decades.

#### *A case for economizing natural resources?*

68. Of course, exhaustible natural resources have to be used in an economical way, as does everything else that is not freely available in unlimited quantities. The question to be asked is the less trivial one of whether there is a convincing general case for economizing exhaustible natural resources in the sense of special arrangements—such as taxes or direct regulation—designed to achieve a rate of extraction lower than that which results when extraction and consumption are limited only by the rule that all social costs, including environmental damage and other external costs, must be covered.

69. In order to pose the question as sharply as possible, one may consider the important and topical example of oil and natural gas. Expert opinion varies with respect to timing, but all agree that the remaining amount of oil and natural gas, known and still to be discovered, cannot cover a continued increase of consumption for many decades. Now suppose, for the sake of argument, that one had a perfect socialist international order, with full public control of the use of natural

resources and acting on the maxim that the interest of coming generations should weigh as heavily as that of the current generation. In this hypothetical situation, one asks whether the policy would be different from that which is now being pursued; whether the ideal international authority here assumed would make a strong effort to hold down the consumption of oil and gas in the interest of future generations.

70. As previously mentioned, experience seems to show that private owners of exhaustible natural resources tend to act on the assumption that future technological development and the rate of discovery of natural resources will become less rather than more scarce as time passes. Our question then is whether a fully socialized decision process would lead to a more "conservationist" result.

71. The answer must be that the result might be either way. It cannot be known *a priori* whether a social husbanding of exhaustible resources would be more or less restrictive (more or less "pessimistic", if you like) than a private one.

72. This is not meant to imply that the solution given by the market mechanism is particularly desirable, or even "optimal". The point is that both the private-enterprise and the socialist decision-maker have to make a judgement, which can at best be only an informed guess, with regard to whether any particular natural resource is going to be more or less scarce in future than it currently is. All one can say is that, presumably, the socialist decision-maker will be inclined to take a somewhat longer view, which should lead to a somewhat slower use of the resources concerned. But it would be an open question whether, in retrospect, when the future has become the present, this more cautious policy would have been well-advised.<sup>12</sup>

73. For instance, imagine that Jevons' famous book, *The Coal Question*<sup>13</sup> (1866), had been taken seriously, and that a policy restraining the use of British coal reserves had been initiated. In retrospect, it was undoubtedly fortunate that no well-meaning, but misguided, fear of resource depletion was at that time allowed to limit the rate of progress for the benefit of future generations.

74. A more modern example may be seen in the change, in the past two decades, in the orientation of conservation policy in the United States of America.

75. Originally, the concern of the conservation movement was directed towards three problems: (1) to economize exhaustible resources; (2) to prevent over-exploitation or other deterioration of the non-exhaustible, but limited, resources (for instance, erosion of good agricultural land); and (3) to conserve the

natural heritage, such as landscapes. Very broadly, the current conservation movement is about to give up item (1) as a goal, which is no longer quite relevant in view of technical developments; item (2) has been preserved more or less unchanged; and item (3) has acquired far more weight in the programme, owing to the interest in pollution and other problems of environment. It is characteristic that the fight against the Alaskan pipeline is motivated by considerations of environment and not of exhaustion.

76. The change concerning item (1), the economizing of exhaustible natural resources, is due, of course, to the explosive development of technology, as a consequence of which the very concept of "exhaustible resources" tends to evaporate. This new orientation in the conservation movement in the United States of America is explained in a book sponsored by Resources for the Future.<sup>14</sup> The authors mention the traditional idea of a dualistic economy, where industry works under the law of increasing returns, thanks to technological progress in the industrial process itself; but, at the same time places ever more voracious claims on the limited amounts of fossil fuels and metals etc., which obey the law of diminishing returns. And they continue:

"These earlier, simplistic views of a world divided into two economic sectors—one progressive, but recessive, the other regressive and dominant—have continued to govern economic thinking down to the present time. Yet they . . . border on the archaic. The transformation of materials into final goods has become increasingly a matter of chemical processing. It is more and more rare for materials to be transformed into final products solely by mechanical means. The natural resource building blocks are now to a large extent atoms and molecules. Nature's input should now be conceived as units of mass and energy, not acres and tons. Now the problem is more one of manipulating the available store of iron, magnesium, aluminium, carbon, hydrogen and oxygen atoms, even electrons. This has major economic significance. It changes radically the natural resources factor of production for societies that have access to modern technology and capital."<sup>15</sup>

77. This text, written in 1962, was an early and clear recognition of a new tendency in modern technology. This tendency was further confirmed in the subsequent decade, with the possibilities now more distinctly envisaged of extracting metals, energy etc. from materials—rock, the sea-bed, sea-water—where they exist in large amounts, though in an extremely low degree of concentration. To give just one example: in ordinary sea-water, there is one atom of the hydrogen isotope deuterium for every 6,500 atoms of ordinary hydrogen, and by weight deuterium makes up 0.003

<sup>12</sup> But note that the discussion is about natural resources for material production. What is said here does not necessarily apply to resources such as landscape or recreational facilities.

<sup>13</sup> William Stanley Jevons, *The Coal Question: an Inquiry Concerning the Progress of the Nation, and the Probable Exhaustion of our Coal Mines*, 2nd ed., revised (London, 1866).

<sup>14</sup> Harold J. Barnett and Chandler Morse, *Scarcity and Growth: The Economics of Natural Resource Availability*, for Resources for the Future (Baltimore, Maryland, Johns Hopkins Press, 1963).

<sup>15</sup> *Ibid.*, p. 237.

per cent of sea-water. Yet, it is this utterly small part of the sea-water which, in the fusion reactor of the future, is designed to provide practically unlimited amounts of energy.

#### *Special cases*

78. It was argued above that the world is not entering a period of generally increasing scarcity of natural resources. But this argument, of course, does not rule out the existence of special cases. In order to qualify as a genuine exception, a specific material would have to pass a fourfold test: (1) it must be certain, or probable, that the remaining deposits, known and unknown, are quite limited in relation to current annual consumption; (2) it must be clear that the existing quantity cannot, without disproportionate cost, be conserved by way of recycling; (3) the material in question must be needed for purposes which are undoubtedly important; and (4) it must be probable that, for these important uses, no economically acceptable substitutes can be found.

79. Materials which are, or threaten to become, scarce in this full sense do exist, but they seem to be few in number. Helium is often mentioned as an important example, and as a strong case for husbanding by international action. Phosphate rock for fertilizer has also been mentioned, although the need for husbanding is probably for a more remote future. The known reserves of mercury, extractable at a "reasonable" price, are said to be sufficient for only a decade or so, but the

possibilities of finding substitutes seem to be greater than was previously thought. In addition to these three materials, there may be other examples of which the present writer is not aware.<sup>16</sup>

80. There is one other situation where a strong case can be made for restraining consumption of a material for some time. This situation arises when the effectiveness of a given exhaustible resource can be expected to increase considerably once a new, emerging technology has become operational. The one prime example of this somewhat exceptional constellation of circumstances is that of uranium, the energy-generating capacity of which will increase a hundredfold the day the fast-breeder reactor takes over.

81. There appears to be a similar situation with regard to geothermal power. In recent years, the amounts of known reserves of underground vapour and hot water have increased conspicuously; and as a response to these discoveries, new and more effective methods of multipurpose use of this heat energy are being developed. But this development takes time; and it might, therefore, be wise to delay the actual tapping of this energy until a new technology for its utilization has become operational.<sup>17</sup>

<sup>16</sup> However, opinions among experts differ. In a communication to the author, David B. Brooks, Department of Energy, Mines and Resources, Ottawa, dismisses the fear of depletion of helium and phosphate, and considers caesium a more serious case of near-absolute limitation of supplies.

<sup>17</sup> See Joseph Barnea, "Geothermal power", *Scientific American*, vol. 26, No. 10 (January 1972).

## ON THE USE OF MODELS AS INSTRUMENTS IN FORMULATING POPULATION POLICIES

*Hannes Hyrenius* \*

1. In the discussions of recent years on the growth of population, economic development and expansion, the exploitation of natural resources and problems of environment, writers have begun to employ simplified world pictures in the form of so-called "models". The purpose of the use of these "world models" is to attempt to make clearer than hitherto the implication of these problems and, if possible, to improve society's capacity to formulate its economic, social, demographic and other policies.

2. The development of models of social conditions and social evolution has been influenced by the development of econometric methods, which were, and are, mainly concentrated on economic phenomena in the strict sense. The facilities available at the beginning were of a mathematical and statistical nature. More general models could be produced, however, when computers and data technique came into being as a means of assistance.

3. The earliest attempts at models of social development were mostly deterministic (non-probabilistic) in the sense that relations and connexions were fixed. This restriction was soon eased, when work was carried out on several alternative levels and with several sets of parameter values. Data techniques made it possible, however, to introduce variations into the individual components by distributions combined with stochastic techniques and also by adding other kinds of random disturbances.

4. The various techniques now available have been used for building comprehensive models with very high levels of ambition. These models, which view human society as a system, generally include the three main factors—natural resources, population and capital—as well as an increasing number of other phenomena and subfactors.

5. The possibility of including in one model all "essential" conditions and variables will, of course, depend upon the further development of technique. If model-building is to serve practical purposes in decision- and policy-making, one must be able at each stage to judge the capacity of the instrument, its degree of generality, its sensitivity and its uncertainty (margins of error). One must also be able to judge how useful the

method is in different sectors and areas of the global society.

6. The development of comprehensive models presupposes a close collaboration between different disciplines of a methodological as well as substantive nature. Reciprocal action has taken place here, and even partial, insufficient and defective efforts have had an encouraging effect on the development of methods. At the same time, increasing interest has arisen within politically responsible circles and in the general public.

7. The aim of this study is to find out whether the types of models developed so far—or types which can be envisaged—can be used as instruments in formulating population policies. Two series of questions arise in this respect:

(a) That of how one defines population policy, what demographic factors and processes one perhaps wants to influence, and what population-related phenomena and processes should be included under the name of economic, social or other policy;

(b) That of determining what properties are required of an instrument if the purpose is to elucidate and compare the effects of different alternatives in population policy.

8. A closer examination was made of what one can reasonably demand of a model under various definitions of population policy. As expected, the study showed that the demographic factors are so strongly related to economic, social and other conditions that even a very narrow definition of population policy requires that these relations be duly taken into account. This conclusion in turn leads to a demand for what are described in the following section on model definitions as "comprehensive dynamic demographic-economic-social models" (DESMOD), regardless of how one wishes to formulate the notion of population policy.

9. As concerns the properties required in such a DESMOD, only a couple of observations can be made here. Further views are put forward in the following section.

10. The interplay of the various factors must be looked upon as a system, from which it follows:

(a) That all factors judged necessary, according to the criteria laid down, must be included;

(b) That these are indicated and measured in correct (unbiased) forms and measurements;

\* Demographic Research Institute, University of Gothenburg, Sweden.

(c) That relations and feedback loops are included correctly and to the extent necessary;

(d) That all constants, parameters, relations and feedbacks are quantified in a satisfactory way.

What these individual requirements signify in detail cannot be stated here, of course. It may be pointed out, however, that the degree of ambition can be varied in accordance with the problems under study in separate applications and uses of the model.

## REVIEW AND APPRAISAL OF SELECTED MODELS

### *General discussion*

11. During modern times a large array of methods and scientific techniques has been developed which can be used in analysing economic, social, demographic and other aspects of human society. Statistical methods have, of course, played an important role in describing and analysing past and present conditions and trends. Aggregate data have been analysed and have partially been extended through extrapolations into predictions of various kinds.

12. Data on micro-levels (individual, families, households, firms) have been collected through more and more advanced sampling procedures for the purpose of filling out the knowledge of actual conditions and trends, ultimately with the aim of laying foundations for political action in economic, social, educational, health, cultural and others matters.

13. All these methods and techniques, of course, will be used in the future and will also be further developed to meet new needs. In this respect, computer technique will mean increasing capacity to carry out such analysis. In addition, however, computers offer new possibilities for co-ordinating knowledge from many fields and, simultaneously, handling large numerical materials. This latter aspect is important, because "conventional" methods are usually limited to a very few factors at a time.

14. An example is found in surveys of health conditions, where studies so far have been limited to a stratification by one or two factors at a time among income, profession, social group, level of education etc. By using a computer, one can not only add other ways of stratification and handle several of them simultaneously, but one can study the interplay of the various factors more meaningfully than before. With conventional statistical procedures, such sources of variation may be separated and eliminated in the variable under investigation. Modern computer technique, however, makes it possible also to distinguish and measure "secondary" effects of these sources of variation upon that variable.

15. A realistic approach to analysing the complicated real world leads to a compromise over which factors are to be included and to the concept of a system of variables, conditions and relations. The interrelations among factors are most easily handled by "feedback loops". These feedback loops must be based on a

profound knowledge of the phenomena, and they should be formulated, quantified and tested by means of observed values and possibly, where data are lacking, by postulated values.

16. These considerations describe briefly the modern approach to various areas of knowledge. For the specific purpose of socio-economic policies, and particularly for activities directed towards population matters and population-related problems, techniques have been developed for both special (limited) and more general purposes.

17. The presentation here will be restricted in certain respects. Thus, the role of statistical methods will not be discussed, although they now cover a wide range of techniques specially developed to meet the needs in analysing socio-economic problems. As for "models", no attempt is made to enter into presentation or criticism of special fields other than that of population (taken in a wide sense). It should furthermore be observed that the discussions are limited to documents and project reports available before the end of 1973.

18. As pointed out by way of introduction, the various population factors are in general so closely connected with economic, social, cultural, religious and other factors that these cannot be overlooked in the formulation of social measures intended to influence the population factors themselves. Added to this is the fact that by means of such measures, once they are put into operation, one gets, to a considerable extent, repercussions on other sides of social life—directly or, with a certain lapse of time, indirectly.

19. These circumstances lead to the requirement that if it is to be possible to develop the model constructions into analytical instruments in policy-making, they must, as a rule, be of the advanced multifactorial sort described above as comprehensive dynamic demographic-economic-social models, "DESMOD".

### *Models developed at the Massachusetts Institute of Technology*

20. If a number of efforts, in connexion with econometric research, to develop more general models are disregarded, the first large-scale model seems to have been what later came to be termed the "Limits to Growth" model.

21. The initiative was taken by a group formed in 1968, the Club of Rome, an informal organization whose aim is to promote interest in and knowledge of fundamental factors in the current system of life and their simultaneous interactions—factors of an economic, social, political, physical and biological nature—and to bring this new interest to the attention of politicians and the general public. In the search for suitable ways to throw light on the present and future predicament of mankind, it was decided to concentrate on the method, "systems analysis", developed at the Massachusetts Institute of Technology (MIT). These methods, which emanated in the first place from Jay Forrester, were originally designed for problems of business economics, but can also be applied in other fields.

22. The method amounts simply to this, that the relations that are considered to apply between the different factors/variables included in the system are programmed for a computer. An important technique here consists of the use of feedback loops, by means of which the interrelations are given the form of a number of modifiers. If the various relations are allotted, observed or postulated quantitative values, the system can be brought to imitate a more or less realistic "world".

23. Forrester's first draft of a World Model comprised a limited number of basic factors (population, natural resources, food production, industrial production, capital, pollution and overcrowding). After modifications and expansion, a "World 2" was published in his book *World Dynamics*.<sup>1</sup>

24. A team under the leadership of Dennis Meadows continued the work and built out the various subsectors in different respects. Efforts to quantify conditions and relations were broadened. In 1972, the results were reported in *The Limits to Growth*.<sup>2</sup>

25. The publication of this book gave rise to an enormous world-wide discussion. The *problematique* discussed in the book turned out to be of great general interest. Part of the misdirected criticism that appeared can probably be attributed to the fact that the technical report was not available. Even a year and a half afterwards, this report is to be found only in a restricted number of copies in mimeographed form.

26. Criticism has been directed against the MIT models from a number of different branches of science. A comprehensive account thereof is provided by a research team at the University of Sussex,<sup>3</sup> to which readers are referred. In connexion with this, a couple of brief observations are made below.

27. The criticism put forward from various quarters includes a great number of constructive suggestions on how to improve the models while retaining the technique of systems analysis, or by using other methods. As a result of this, a number of new studies and research projects have been begun.

28. The authors of *Limits to Growth* themselves point out that model behaviour must be in reasonable agreement with real world behaviour. This implies the need to assemble time-series data on the variables in the real world from 1900 to 1970. The examination by the University of Sussex team suggests that the MIT models do not, on the whole, satisfy this requirement. This is in part a problem of data and in part, a question about relationships.

29. Each sector has been examined in the Sussex study by specialists and is treated in six chapters. In the

first chapter, "Malthus with a computer", by Christopher Freeman, it is claimed: "With the exception of the population sector they (the assumptions) are generally found to be unsatisfactory."<sup>4</sup> This statement, of course, is made with different levels of ambition for the various sectors.

30. The judgement of the Sussex team that the population sector is satisfactory is, in the present writer's opinion, not acceptable, as is shown below. Special requirements must be set up especially for population, and therefore the population sector, too, must be considered unsatisfactory, even if it is better and more detailed than appears in the text report, *Limits to Growth*.

31. In the Sussex University report, Cole describes the most important general features of the world models as:

- (a) Description of the world as a closed system with no external influences;
- (b) Choice of major parameters;
- (c) Major interactions of the feedback loops;
- (d) Use of world averages for all parameters;
- (e) Amount of detail (the number of relationships);
- (f) Non-probabilistic nature of its predictions.<sup>5</sup>

32. The Sussex group's analysis is carried out, among other things, by alternate runs, by which means it is made clear that the systems analysis method is highly sensitive to changes in the input values. From this it also follows that coarseness short-comings and direct errors in the construction of the relations and in the quantifications may have great and possibly completely disabling consequences.

33. For "World 3", the Sussex report gives an account of runs with a division into developed and developing parts. It is pointed out, too, that deficiencies appearing through these exercises need not automatically lead to the rejection of a whole subsystem. Since the sensitivity of systems analysis is great, as demonstrated by several authors, a more careful expansion of interrelations and feedbacks ought to be able to correct certain short-comings.

34. A large number of constructive proposals are put forward in the various chapters of the Sussex report, and may give occasion for improvements and, in part, for separate projects.

35. As a comprehensive judgement on the "World 3" model, the following points may be considered and made the objects of research contributions:

- (a) The aggregation is too strong and involves the blurring and possible disappearance of the heterogeneity in all the subsectors. At the same time, it renders difficult or impossible an assessment of the various change factors that follow an acceptable extrapolation;
- (b) In the model structure, a number of essential basic factors are lacking: social structure, technical level, educational level, morbidity and, not least impor-

<sup>5</sup>*Ibid.*, p. 25.

tant, a value system and a price mechanism that can cover essential features in the economic processes and in social behaviour;

(c) The model is given out to be a dynamic one, but in several respects it is actually static or almost static. This is precisely the meaning and result of the fact that certain components essential for human society are missing;

(d) The use of geometrical/exponential growth in one or more components leads of necessity to catastrophic situations, even if the rate of growth is in itself small. This applies both to growth in the population and to growth in industrial production, and it applies to individual goods and to growth in animal species and plants;

(e) The techniques used in measuring the various phenomena are, in some parts of the model, very poor and misleading;

(f) The tests and adjustments made so far are carried out on units that are too concentrated and too heterogeneous. They are, therefore, to an unknown extent, meaningless for judging the validity and capacity of the models;

(g) Special efforts must be devoted to the development of methods for including different kinds of flows of materials, commodities, labour force, non-working population, capital etc.;

(h) Special models of micro-types should be inserted step by step in all sectors possible, with a view to adding to the disaggregation and precision of the internal structure.

*The population sector in the "World 3" model*

36. Since the population is the centre for the whole of the model work, it is particularly important for the population sector to be well constructed and quantified. This is, in fact, of fundamental importance for the whole model by reason of the arrangement of the system, and not least as a consequence of the great sensitivity of systems analysis to errors in the construction itself, to deficiencies and coarseness in the measurement of phenomena, to errors in quantification and to omissions of relevant subfactors and feedbacks. The population sector has been criticized by the Sussex group and by the Demographic Research Institute at Gothenburg, among others.

37. The first MIT models did not make use of any age grouping at all. Consequently, births and deaths were expressed by crude rates only. Furthermore, the labour force could not be measured properly. In subsequent models ("World 3", underlying *The Limits to Growth*), various improvements have been made. The handling of the demographic factors, however, still leaves much to be desired, if judged from even moderate aspirations of demographic techniques.

38. Mortality is expressed by one parameter only, the life expectancy (mean expectation of life for the new-born). This appears to be quite unsatisfactory.

From a "life expectancy normal" of 28 years, four multipliers are supposed to take care of the influence of living conditions (food, health service, crowding and pollution). This influence is carried out in a complicated and controversial way.

39. Fertility is treated through an interesting combination of the fraction of fertile women and total fertility, where the latter is built on desired total fertility and birth-control effectiveness. The multipliers from living conditions are based on the influence of industrial output and perceived life expectancy. Even if the logical structure of this approach were acceptable as a beginning, it is hard to understand how a quantification of the various relations can be anything better than subjective collections of information, assembled from heterogeneous conditions. A combination must therefore offer risks of errors of many kinds.

40. For a more detailed discussion reference may be made to the Sussex report. The capacity of the model is summarized in the table given below by simply comparing the growth of the population 1900-1970, according to United Nations official estimates and those derived from "World 3" (standard run).

COMPARISON OF UNITED NATIONS ESTIMATES WITH "WORLD 3" MODEL

Year	Population estimates (millions)		Annual increase (percentage)	
	United Nations	World 3 model	United Nations	World 3 model
1900	1,650	1,610	0.60	0.89
1910	—	1,760		0.82
1920	1,860	1,910	1.06	0.85
1930	2,069	2,080		
1940	2,295	2,380	1.04	1.35
1950	2,486	2,740	0.80	1.41
1960	2,991	3,210	1.85	1.58
1970	3,632	3,790	1.94	1.66

41. It should be recalled that the model was manipulated so as to conform with a few initial data. In spite of this, the agreements must be said to be fairly poor. Using the model on the unknown future after 1970 is therefore a highly risky adventure.

42. The birth and death rates that have resulted in these population growth rates behave according to the model, in a rather peculiar manner, and deviate, in part considerably, from what is known (or what is believed known for the beginning of the period).

43. "World 3" works with three different ways of taking age into account. Either no age division is made at all, or a division is made into 4 large age groups, or into 15 age groups. A certain improvement naturally ensues with age differentiation where measurement of natality and mortality is concerned. That the result, nevertheless, cannot be regarded as satisfactory must be attributed to the construction and technique of measure-

ment, the multiplier arrangement and the quantification of this. Noteworthy and sometimes strange effects are obtained by the use of a special discontinuity technique.

44. The labour force is calculated in the model as 0.75 of the whole population between 15 and 65 years. Actually, the labour force is not used as an integrated factor in a production function, but is included only secondarily in a "job sector" within the capital subsystem. The author's explanation of this is that as there has always been a labour surplus, on the global level, the labour force then becomes negligible in comparison with capital generation. This unrealistic outlook is coupled with the assumption that there are unlimited possibilities for migration on the earth. No account is taken of the quality of labour. This way of treating production—which, of course, becomes of vital importance for the whole global system—has been strongly criticized by P. A. Julien and Christopher Freeman in the Sussex report.<sup>6</sup>

45. With such a formulation of the economic system, of course, there can be little claim of ability to measure the labour force correctly. A more realistic approach must naturally take account of the restricted mobility, or in some cases, immobility of the labour force and with it, in fact, of the whole population, together with its physical and mental "quality". This presupposes a distribution of the population by sex and age, as well as by marital status and family/household type, health conditions (delimitations due to morbidity and disability), school and occupational education etc. All these are lacking in "World 3", but it appears possible that they could be successively built into a more differentiated model design for homogeneous populations/societies.

46. In their comments on the "World 3" model, the Sussex group end the discussion of the population subsystem by stating: "The model is not really forecasting the most likely world population sizes. Rather, the population subsystem is a means of generating plausible population figures to use as input for the other subsystems, and, as such, could have been made much simpler."

47. This, in the opinion of the present writer, is like placing the cart before the horse. The alpha and the omega of the model ought to be the human factor in the system.

48. From the demographic point of view, a detailed age distribution (5-year groups) is necessary, of course, and it should be extended to high ages. For the study of employment, differentiation should also be carried out by sex; furthermore, family/household structure should be included in a suitable way, so that unpaid female participation in working life could be taken into account in the model.

49. Further, for calculating the consumption of goods and services, an age differentiation of the population must be made, since most of the elements here are age-specific and, in part, strongly bound to sex and

household. Where services are concerned, these include infant and child care, educational organization, sick and health care, social welfare, old-age care and housing. These, in turn, are important for the structure and composition of production and trade and business and non-industrial services, as well as for saving tendencies and capital formation and for the level and directions of investment.

50. On this, the MIT report referred to in paragraph 25 states:

"... we consider the exclusion of labour to be one of the least satisfactory simplifications of the global model, primarily because of the social implications of unemployment. While inclusion of an explicit labour force and representation of the causes and consequences of unemployment are unlikely to change the basic behaviour modes of World 3, these additions would make the model much more relevant to studies of social welfare and political stability. Global unemployment is an immense problem today and is expected to worsen over the next several decades. It would be useful to extend the model to include the causal mechanism in which unemployment is involved."

#### *The International Labour Organisation "Bachue" models*

51. A large-scale research project was begun at the International Labour Office in 1972, within the framework of the World Employment Programme of the International Labour Organisation (ILO). The final aim of this project, the over-all title of which is "Population and Unemployment", was stated to be to enable Governments, especially those of the developing countries, to take more effective account of population matters in employment policies and vice versa.

52. The means of attaining this goal is to construct a model which would make it possible to analyse conditions and tendencies in the labour force and employment, as well as the principal phenomena and variables which influence them. In other words, it is a question of a fairly general model in which, however, some phenomena will be given a less prominent role than in the MIT models.

53. The first stage of the development work has been carried on by Richard Blandy and René Wery, in consultation with experts from the Sussex group. The model is based on the technique of systems analysis. A detailed report has not yet been published, but the project's main properties have been presented in preliminary papers.<sup>7</sup>

54. The ILO project, named after Bachue, the Colombian goddess of love, fertility and harmony between nature and man, consists of two parts. One part consists of research studies dealing with important

<sup>7</sup> See R. Blandy and R. Wery, "Bachue-I, The dynamic economic-demographic model of the population and employment project of the World Employment Programme", in *International Population Conference*, vol. 1, pp. 17-51 (Liège, International Union for the Scientific Study of Population, 1973).

<sup>6</sup> *Ibid.*, pp. 66-79.

elements in the network of relations between population and employment behaviour. Parallel to these, efforts are being made to build quantitative simulation models reflecting this network. The initial concept of an economic-demographic system was first formulated in a model called Bachue-1. This is described as, first and foremost, a learning experience. The model is designed to represent a high-fertility developing economy. A number of countries have been engaged in working out specific applications, the first of which is Bachue-Philippines.

55. It is expected that the forthcoming experience from these country-models will serve as an important feedback in improving the theoretical structure of Bachue-1. In this way, the substantive studies will aid the process of successive revision of the model for understanding the population-employment problems in developing countries.

56. Since the Bachue models employ the systems analysis method, they can be said, in principle, to have a number of the advantages and deficiencies that have been quoted above in reference to the MIT models.

57. With regard to the effects of the strong aggregation, it may first be mentioned that these have been diminished somewhat, in part by limiting the aim and concentrating upon conditions only in the less developed part of the world, and in part by working, in certain variables, with a rather greater differentiation.

58. Both these circumstances, however, lead to other kinds of difficulty. Quantification can naturally only be done with data from countries where fairly reliable data are to be found. Here, data on Mexico have been used in preference, but data from a couple of other Latin American countries have also been used. This evidently gives a bias when it is a question of representing the whole of the less developed world. Nor is the difference in socio-economic structure given its due.

59. From the methodological aspect, difficulties arise in measuring and quantifying migration and other flows within the economic subsystem. An important advance in the Bachue models, however, is the way in which rural and urban sectors of population and economy are separated.

60. The prototype of the Bachue models consist of three sectors, the demographic subsystem, the educational subsystem and the economic subsystem.

61. Of the first it may be said that it includes the population by sex, age, location (rural/urban) and activity (employment or not). Mortality is indicated quite simply by means of the mean expectation of life, from which age-specific mortality rates are obtained with the aid of the United Nations model life-tables.<sup>8</sup> In its turn, the life expectancy is assumed to be dependent upon the average household income and to rise from the initial level of developing areas to a level

corresponding to current conditions in the industrial countries.

62. As for the birth rate, the models work with two components, desired number of births and "uncertainty". The desired or planned number of births is assumed to be determined by means of the following "modifiers": child mortality (positive); average educational level of adults (negative); opportunities for women to work in modern sector jobs (negative); proportion of unpaid family workers in the labour force (positive); average educational level of children (negative); and average household income (negative).

63. This is a far more differentiated approach than that of the MIT model, "World 3". It carries with it, however, the risk of considerable accumulation of systematic errors as a result of difficulties in determining the interaction between influencing factors. Also, the quantification for a heterogeneous population/society seems difficult, risky and, in part, impossible, just as is the case with the MIT models.

64. By "uncertainty" is meant the effectiveness of family planning practice. This is assumed to depend, among other things, upon the educational level of adult females. One innovation is the introduction of a policy variable in the form of the rate of spread of modern contraceptive technology, which is assumed to be subject to governmental control. A further factor is the difference between rural and urban, which is taken into account through an assumption about migration.

65. A special method has been worked out for handling net migration from rural to urban sectors. Migration is based in the first place on the propensity of males in the working ages to migrate. The tendency to migrate is assumed to be affected by educational level, income and employment-related variables.

66. The presentation of the Bachue models contains a comprehensive, though not completely enlightening, discussion of labour force definitions in a society with both a traditional and a modern economic sector. The meaning is that previous models only took account of one-way causal connexions in the economic-demographic processes, while Bachue seeks to analyse economic-demographic interactions in a complex set of realities whose interconnectedness enhances the explicative value of the model. Further, Bachue-1 has three main distinguishing features:

(a) First, it is highly endogenous: fertility, mortality, rural-urban migration, schooling propensities, productivity, income distribution and consumption patterns—all respond endogenously to the behaviour of the system;

(b) Secondly, it involves a high level of disaggregation. Population is broken down by age-sex groups and activity status as in some earlier models; its simultaneous breakdown by rural-urban residence and levels of educational attainment is a novel feature. Similarly, the economy is disaggregated into a national accounts expenditure framework with an input-output matrix being

<sup>8</sup> *Age and Sex Patterns of Mortality, Model Life-tables for Under-developed Countries* (United Nations publication, Sales No. 1955.XIII.9).

used to derive sectoral "value-added" and employment. Such disaggregation permits a more rigorous analysis of the impact of factor supplies on output and employment and their feedback on demographic variables;

(c) Thirdly, it makes an explicit attempt to represent economic dualism (the coexistence of modern and traditional sectors) and to estimate the size distribution of personal income.

Simulations on Bachue-I have shown that fertility reduction might be seen as one of the most crucial causes reducing economic dualism.

67. The treatment of the educational subsystem is linked with a report published by the Organisation for Economic Co-operation and Development (OECD),<sup>9</sup> in which a division is made mainly according to the number of school years. A system of feedback loops integrates education into the total system. The combination of rural/urban distinctions implies a clear improvement as compared with other attempts at general and sectoral models.

68. It is obvious that the Bachue model includes several factors and feedbacks which are missing in the model "World 3", in both the population and the economic sectors. In addition, education is included.

69. It is too early to review in this presentation the details of Bachue and to form an opinion of its value for various purposes. It would appear, however, that the successive improvements of the model through a planned dialogue between the basic model and the substantial country studies will make it possible to obtain a useful instrument for analysis and policy-making in the types of countries concerned. The quantification difficulties of parameters and linkages are, however, immense.

70. One step would be to combine the experiences and models thus obtained with a revised future version of the MIT model "World 3". This will not be an easy task, but it can be done. It will, as a matter of fact, improve the Bachue model in fulfilling its own objectives, as well as help to produce a general model suited not only for developing countries, but for a variety of societies which are homogeneous with regard to demographic, social and other aspects.

71. It appears important and urgent that health conditions (acute illness, invalidization and inability to work) should be included explicitly in the model. Special studies are being carried out to solve the methodology and assemble data for this extension by the World Health Organization and by research institutes.

#### *Other selected models*

72. There are a number of models and study projects to be found which are linked in limited respects with the theme of this report, that is, to the extent to which model methods can be used to obtain an improved basis for decision about political measures.

73. A number of projects are considerably older than the recent discussion on the future of mankind, while some studies have been directly inspired by the MIT models—often as a result of criticism of the latter. Certain models are independent approaches using specific methods other than systems analysis.

74. Although a number of econometric models have a general aim, they are, as a rule, greatly restricted with regard to the variables included, as well as the form and extent of the interrelations between the various phenomena and factors. These models, therefore, do not answer to the definition of dynamic DESMOD. At the same time, however, it is clear that relatively simple models may at times, under specific conditions, make a contribution of direct value in the interpretation of a phenomenon. They may thereby, in theory, also serve as a method in decision-making.

75. Further mention should be made of a group of models which were not directly constructed to be instruments in decision-making, but only with the lesser ambition of giving a better picture of a phenomenon. In the population sector there are thus to be found certain simulation models which, placed in a wider context, can serve as a means for the analysis of population-related social problems and even be included as a subsector in a general model. (It should be emphasized that the models reported on in this section form but a small and unrepresentative selection, limited by the short time available for drawing up this report.)

76. First, there is a type of model for demographic use which has played a large part, and still does, in planning in less developed countries where no precise information about mortality conditions is available. Special model life-tables have been constructed by the United Nations, by the Office of Population Research at Princeton, and by other organizations. From these sets of life-tables it is possible, if one or two estimates of the mortality level are available, to choose a suitable table for use in analysing and forecasting the population of a specific country. Suitable estimates might be, for example, one of infant or child mortality and one for an adult age-interval. This technique has played an important role in national planning in such areas. These model life-tables are also being used for other purposes, e.g., as part of more general model approaches.

77. Recently, efforts have been made to construct similar sets of tables for fertility. In this way, even the statistically less developed areas can analyse and forecast their demographic conditions for a period ahead. As independent observed data become successively available these methods, of course, will lose their importance. On the other hand, such tables serve a purpose in long-term analysis and in connexion with more general models. They therefore constitute an important ingredient in the building up of general demographic-economic-social models.

78. In recent years, a number of different models have been worked out to simulate reproduction or certain components of it. The pioneer effort would

<sup>9</sup> Organisation for Economic Co-operation and Development, *Som: A Simulation Model of the Educational System* (Paris, Centre for Educational Research and Innovation, 1970).

seem to have been made by G. Orcutt and his colleagues in 1961.<sup>10</sup> Later, various attempts followed, in part to work out more detailed models of fertility and in part to obtain general models of the whole reproductive process. Among all these models, a few may be touched on briefly here.

79. A deterministic model, called FERMOD, has been developed by R. Potter and J. Sakoda.<sup>11</sup> This has been used, among other things, for the analysis of fertility and family planning programmes. More exhaustive is the stochastic model, POPSIM, worked out at the Triangle Research Institute, Chapel Hill, North Carolina.<sup>12</sup> A modified form of this is that called REPSIM by M. Sheps and his colleagues.<sup>13</sup> Both these versions aim at relatively detailed descriptions of the reproduction of human populations. There have been a number of applications. Thus the models have been used not merely for analysing current reproductive conditions in various populations, but also for comparing different methods and policy projects with reference to birth control.

80. Simulation models of fertility in combination with nuptiality and mortality have been further developed at the Demographic Research Institute, University of Gothenburg.<sup>14</sup> Certain versions of these models deal with the conditions where birth control is absent, while other models have in view the conditions in a country where birth control is fully carried out. Various functions in birth control have been studied. The possibility of simulating the transition during different external circumstances has been arrived at by these means.

81. A research project at the Université Catholique de Louvain has been planned for a very comprehensive and detailed simulation model, the direct aim of which is to describe the course of transition from high and uncontrolled levels of mortality and fertility to low controlled levels and it can thereby answer the need of the developing countries to judge the course of events

on different assumptions about the effectiveness of the control of mortality and fertility, respectively.

82. As an example of a model with a limited purpose, mention may be made of a project developed at the University of Chicago by Donald J. Bogue, Scott Edmonds and Elisabeth J. Bogue.<sup>15</sup> The project includes computerized applications to the setting of targets and quotas for family planning programmes.

83. Although the model is relatively simple in its scope, it has great flexibility. What is particularly important is that it can handle the dynamic process in time in all essential variables. Among these are counted not only fertility, mortality, migration and marital status, but questions of birth control, such as the effectiveness of the methods, the average time for use of preventive technique and the effectiveness of the actual use of different methods. If the latter factors are treated from a more general perspective, there is evidently a possibility of judging alternative methods in order to carry out birth control programmes in countries with different starting-points and varying objectives. To sum up, it may be said that a model of this sort can well fit in as a sector in a more general programme.

84. A number of research projects have been initiated as a consequence of the discussion and criticism that followed the publication of *The Limits to Growth* (see paragraphs 24-27). A couple of projects were begun even earlier. Some have developed their own methods for analysing the growth problems.

85. The diversity of these projects makes it impossible for the time being to find out what would be the integrated and co-ordinated knowledge available through all these studies. This is particularly the case as, with a few exceptions, only preliminary and incomplete progress reports have been published.

86. From the point of view of this report, it should also be observed that relatively few of the projects are designed for developing formal models which can serve as decision instruments in analysing and comparing different political measures. On the other hand, it is evident that a great many of the non-model studies contain observations and conclusions of high relevance and importance for the operating of models and thus for the ultimate formulation of policies.

87. Directly connected with the Club of Rome are the following:

88. In Latin America, a large project has been initiated in order to develop a separate world model, with its starting-point especially from the situation and valuations of the developing countries.<sup>19</sup> A number of Latin American countries are taking part in this, under the leadership of A. G. Herrera. The work begins with a critical analysis of the MIT model, after which the authors design their own model. Growth hypotheses have been developed and efforts are being made to estimate the possibilities of development for the less developed countries over a period of 30-35 years ahead. The prospects of economic equalization between rich and poor countries are judged, among other things, in the light of the consequences for the environment.

89. A project of a special nature is "Population Doubling Problems", under the direction of H. Linnemann, with J. Tinbergen as adviser.<sup>20</sup> This is not primarily a systematic model construction, but an analysis of necessary programmes and decisions which must be taken now, if some of the most difficult problems of resources under a doubled world population are to be mastered.

#### CONCLUSIONS

90. The extensive criticism to which certain model experiments have been exposed from seriously engaged scientists and technicians, as well as from generally interested but less expert persons and representatives of mass media, has not been merely negative. A number of constructive points of view and suggestions have been put forward. Some of these have resulted in projects designed to improve, in certain points or subsectors, what has already been published. Furthermore, completely new ideas and methods have been launched for investigating future development.

91. The present paper gives an account of a study of a number of models already described in some degree,

as well as of a limited number of critical reviews of such models. It should be emphasized that the selection of material is strongly affected by what was actually available during a short period up to the end of 1973.

92. This study gives the investigator grounds for the following concluding statements. The points of view and proposals are entirely the investigator's own.

93. The models and methods worked out so far, as well as the different tasks of expansion and improvement of these which are now going on, are not yet of a nature and capacity to enable them to function as instruments in a deeper analysis of demographic-economic-social problems. For this reason, they cannot currently contribute in any appreciable degree to improving the grounds for decision in the formulation and carrying through of political measures in these areas. They cannot replace parts of current investigation procedure.

94. The development of a general model which, in all essentials, reflects the condition and change factors in population and society is only a first step. *A priori*, one can think of the model as a closed system with its various internal interrelations. The model does not become of practical interest, however, unless it is possible to express the influence of exogenous variables upon the central phenomena. It is only under these conditions that one can expect, through model-building, to arrive at instruments for analysing the effects of alternative measures in the demographic, economic, social and cultural fields. Since the models are by nature mainly built up on quantitative variables, numerical forms must be found for the relations that are to express the effects of the measures taken. These relations may take the form of tables, curves or mathematical functions with sets of parameters. An example of this is the introduction of a policy variable into Bachue for the study of government activities in family planning.

95. The work with general models must be specially directed towards producing such policy relations. To the extent that quantification cannot be carried out, the possibility exists of working with different sets of parameters for alternative forms of measures and alternative effect phenomena.

96. Although the models now available and the projects now under way may appear insufficient as instruments in analysing and comparing alternative policy measures, they may, with somewhat less ambition, be used for what could be termed process-control of the society. This would meet the marked need for evaluating the outcome of ordinary forecasts and projections of populations. Such evaluations have so far been made with rudimentary tools, while a realistic interpretation necessitates a systems approach, incorporating natural resources, labour force, capital, structure of the economic machinery, consumption patterns, social factors, environmental effects etc. Using models, whether general or sectoral, in such ways would serve as an alarm system, indicating when any one phenomenon deviates more than what is considered acceptable or normal. The

need for policy actions could thereby be shown at a suitable time in advance.

97. Research and further development in this highly technical field requires extensive resources and the co-operation of scientists from many different disciplines. What has been achieved so far has been obtained in part through occasionally organized activities at a few large research institutes and through *ad hoc* research teams. Valuable contributions have also been made, however, by small institutes and by individual scientists.

98. For promoting further development research, it appears necessary to make arrangements for co-ordinating already existing projects and initiating research on "gaps" in the research frontiers.

99. It is necessary, furthermore, to provide guarantees that continued financial resources will be available for all subprojects needed. Otherwise, lack of financial resources leads to bias and distortion of research efforts and underemployment of the existing research staff with its valuable knowledge.

100. It would appear that these tasks should, in the first place, be taken care of by the United Nations and those of its special agencies which are most concerned (the International Labour Organisation, the World Health Organisation and the United Nations Educational, Scientific and Cultural Organization). Different forms of organizations are possible, of course.

101. It appears to be highly desirable that already existing research projects at universities and other research organizations should be co-ordinated in order to give maximum use of research staff and financial resources. A possible co-ordinating agency would be the Committee for International Co-ordination of National Research in Demography (CICRED).

102. Regardless of the way in which the continuation of the work is organized and carried on, the formulation, applications and quantifications of the models must be applied to strata (regions, type of society) which are, as far as possible, homogeneous in essential respects.

## ECONOMIC-DEMOGRAPHIC MODELLING ACTIVITIES OF THE WORLD EMPLOYMENT PROGRAMME \*

### *International Labour Office*

1. In 1972, a large-scale research project on population and employment interactions was initiated by the International Labour Organisation (ILO) with funds from the United Nations Fund for Population Activities (UNFPA) and within the general framework of the World Employment Programme. This project currently consists of two interrelated activities: a series of research studies dealing with important elements in the network of relations connecting population and employment behaviour; and an effort to build a series of quantitative simulation models.

2. The series of economic-demographic models is called *Bachue*, named for the goddess of love, fertility and harmony between nature and man in Colombian mythology. The intent of this modelling exercise is to provide Governments in developing countries with either specific country models which can be used to take more effective account of population matters in employment policies, or an analytical framework which can be adapted by Governments in building their own policy-oriented economic-demographic models.

3. After *Bachue-1*, the *Bachue* series will consist of country-specific models. However, to ensure some degree of homogeneity among these country-specific models, it was decided to build *Bachue-1* (the first model in the *Bachue* series) as an experimental simulation exercise. It was in *Bachue-1* that the initial concept of an economic-demographic system was first put on paper.

4. *Bachue-1* will be used as a general model after which the country-specific models will be patterned. *Bachue-1* has three main characteristics distinguishing it from its impressive number of predecessors, which have been developed in various places over the past 15 years. First, it is highly disaggregated: population is distributed by age and sex between urban and rural areas and by educational attainment; and economic activities are disaggregated into a full, national-accounts expenditure framework coupled with an input-output matrix to derive production, employment and value-added by sectors. Secondly, *Bachue-1* has two structural features which distinguish it: an explicit attempt to

introduce economic dualism; and an explicit attempt to estimate the behaviour of the size distribution of personal incomes. Thirdly, the degree of endogeneity in *Bachue-1* is very high: rural-urban migration rates, fertility and mortality rates, schooling propensities, productivity growth, and the pattern of final demands all respond endogenously to the behaviour of the model.

5. *Bachue-1* can be considered foremost as a learning experience from the point of view of computer modelling and as a testing-ground of the relevant existing literature on demographic-economic interactions. It was during this specification of *Bachue-1* that gaps in the base of demographic-economic interactions became evident. In that sense, *Bachue-1* proved useful in identifying areas in which theoretical or empirical knowledge was limited and in which further research was necessary.

6. *Bachue-2*, the second model of the *Bachue* series, is currently under way. It is applied to the Philippines for the following reasons. First, because a consistency input-output employment model for the Philippines is being developed by Erik Thorbecke in connexion with the ILO comprehensive employment mission which was sent to the Philippines in the summer of 1973. It is clear that this economic model could become the base of the economic system in the formulation of *Bachue-Philippines*. Secondly, there is a large body of secondary data which can be used to specify empirically many relationships appearing in the *Bachue-1* framework. The completion of the *Bachue-2* is planned for the autumn of 1975. Some features of *Bachue-2-Philippines* are presented under the heading *Bachue-2*.

7. *Bachue-3* is being applied to a country in Latin America and *Bachue-4* to a country in Africa. From experience gained in data collection in the Philippines, it is considered that access to primary data is of vital importance in the formulation of a comprehensive economic-demographic model. In some cases, specific surveys should be conducted to obtain more information on the interactions between demographic and economic and sociological phenomena. It is hoped that this type of information could be incorporated into *Bachue-3* and -4, which are scheduled to be completed by the end of 1976.

8. At the same time that country-specific models are being built, work is continuing in improving the specification of the prototype *Bachue-1*. It consists of a revi-

\* The original text of this paper was submitted as E/CONF.60/SYM.I/17 to the Symposium on Population and Development, Cairo, 4-14 June 1973; and as E/CONF.60/SYM.III/16 to the Symposium on Population, Resources and Environment, Stockholm, 26 September-5 October 1973.

sion of the framework on the basis of the experience gained in country-specific Bachue models; results from substantive studies in developing countries undertaken under the auspices of the Population Employment Project; and outcome of the other research activities of the World Employment Programme (research on income distribution, technologies, education etc.). It is clear that improvements in certain aspects of the model are necessary. In particular, more policy instruments should be identified and their effects on economic and demographic behaviour quantified, in order to increase the operational usefulness of the model.

9. Furthermore, the computer language used in specifying Bachue-1 is being simplified. At first, it was programmed in Dynamo language, which is based on System Dynamics.<sup>1</sup> Whereas there were important advantages in using Dynamo in the original version of Bachue, the disadvantages in terms of extremely large core usage, difficulty in adapting it to computers available to the developing countries and others, convinced the developers that the model should be rewritten in Fortran language.

10. It is hoped that the country-specific versions of Bachue will be of some use to policy-makers.

#### BACHUE-1: THE PROTOTYPE FRAMEWORK

11. Bachue-1 is a very ambitious undertaking representing the complexities and structural characteristics of developing countries. For this a price has been paid in that knowledge of the quantitative dimensions of behavioural relations in the developing countries is very meagre. Even the qualitative dimensions are not well understood. Bachue-1 is not a representation of any particular country, but a representation of an archetypal developing country in Latin America. It is based on theoretical relations quantified in published research, regression analysis, expert judgement and intuition about Latin American countries.

12. Hence, no empirical interpretation should be given to Bachue-1. The parameters of the theoretical framework were done, using facilities offered by the Dynamo language, to achieve plausible results. Simulation of the model was done under various hypotheses to achieve a feeling for the sensitivity and importance of various parameters.

13. Bachue-1 is comprised of three general subsystems:

- (a) A demographic subsystem including rural-urban migration;
- (b) An education subsystem;
- (c) An economic subsystem.

<sup>1</sup> System Dynamics and Dynamo are attributable to the pioneering work of Jay W. Forrester and others at the Massachusetts Institute of Technology (Cambridge, Mass., United States of America). Dynamo offers some remarkable facilities, including the ease with which non-linearities can be handled, the clarity of its error messages and the irrelevance of programme ordering.

14. A detailed description of the model is not given here. An algebraic formulation of the economic subsystem can be found in annex I. A chart showing the main feedback effects in the model is shown in annex II. What follows is a brief description.

#### *The demographic subsystem*

15. The demographic subsystem consists of a set of accounting identities which trace cohorts of population by five-year age groups, rural-urban location and sex throughout their lives, and a set of behavioural equations which determine births, deaths, migrations and labour-force participation (see annex I). People are born (male or female in urban or rural areas). They either become old or die. If they become older they either migrate from rural to urban areas or they do not. They are either in the labour force or they are not. In the end, they all die. By means of this accounting system, one can trace at each point of time the age/sex/location/labour-force composition of the population, as well as its total size. Behavioural variables classified by age/sex/location in this subsystem are births, deaths, migration and labour-force participation.

#### *Births*

16. In the model, births each year are a function of the average actual number of births that fertile women are likely to have over their lives (by urban and rural areas). This actual lifetime number of births (for rural and urban areas each) is made up of two components—a planned number of births and “uncertainty”. The explanation of the planned number of births is based on the two theories presenting children as an investment good and as a durable consumer good. Explanatory variables retained are mortality rates, average educational level of adults and of children, opportunities for women to work in the modern sector, proportion of unpaid family workers in the labour force and the average household income.

17. “Uncertainty” reflects the degree of effectiveness of family planning practices. It is assumed that without modern contraceptive technology it is not possible to reduce the lifetime average number of births per woman except with a very long delay in marriage. It is also assumed that the average educational level of females influences the effectiveness of birth control.

18. Lastly, a policy variable in the form of a rate of spread of modern contraceptive technology has been introduced. Modern contraceptive technology is assumed to permit families to eliminate “uncertainty” and to achieve their planned number of births.

19. In addition, because of rural-urban migration, it is assumed that migrants bring with them rural birth-behaviour, which is adapted over a five-year period to the prevailing urban (non-migrant) pattern.

20. Lifetime expected numbers of births are then transformed in the model into annual age-specific birth rates.

## *Deaths*

21. Life expectancies by sex/location are assumed to increase slowly as average household incomes increase, reaching developed-country life expectancies at high household-income levels. A slightly longer urban than rural life expectancy was also assumed. Life expectancies are then transformed in the model into annual age/sex/location-specific death rates.

## *Net rural-urban migration*

22. Net rural-urban migration in the model depends upon the migration of working-age males. The propensity to migrate is a function of four variables: (1) the rate of growth of modern-sector urban jobs; (2) the ratio of rural to urban household income; (3) the average educational level of working-age rural males; and (4) a weighting factor (derived from the gravity model of migration) which adjusts the rate of migration obtained from the other variables.

23. Migration rates by age and sex are obtained by multiplying the migration rate for working-age males by ratios representing the proportions that the age/sex migration rates form to the rate for working-age males.

## *Labour force*

24. The determination of labour-force size and composition is one of the main areas of the model on which much more development is needed. There are many difficulties with the concept of labour force as applied to the developing countries which are well known. For instance, because of the importance of the family unit as a production entity in the developing countries, it is often difficult to distinguish "market" work from "home" work or even "work" from "leisure" activities.

25. At this stage of development of *Bachue-1*, the labour force has been calculated by the simple expedient of multiplying each age/sex/location group of the population by age/sex/location-specific labour force participation rates.

## *The education subsystem*

26. The education subsystem again consists of a set of accounting identities which divide the population into those who are in the education system and those who are not, and which trace the respective subcohorts of population through their lives.

27. Each five-year age/sex/location-cohort of population can then be classified according to the highest level of education completed (and according to the level of education in which they are currently enrolled for those age groups attending school).

28. The behavioural equations determining the development of these educational characteristics of the population concern death and migration rates, and enrolment and drop-out rates. It was assumed that there was no difference in death or migration rates between those in school and those outside school. Enrolment and

drop-out rates in primary, secondary and tertiary education are related to household income levels.

## *The economic subsystem*

29. The economic subsystem consists of a general equilibrium, input-output consistency model with supply constraints.<sup>2</sup> The most novel features of the subsystem are an explicit recognition of "traditional"<sup>3</sup> production sectors and the derivation of a distribution of household income by size of income. Beginning with final demand for domestic production by production sectors, sector output levels are computed. Sectoral value-added is derived from the gross output levels; and, lastly, sectoral employment is calculated on the basis of the sectoral value-added and estimates of labour productivity. The employment and production levels for each sector form the basis for estimates of household income distribution. The income of these groups is either taxed away, saved or consumed—completing the circular flow of income and production.

## *Final demand*

30. Final demand for domestic production consists of the sum of consumption by urban and rural household groups defined according to size of income plus investment by households, enterprises and government plus government consumption plus exports minus final imports demanded. Each of these components of final demand is distributed over the productive sectors of the economy.

31. Household consumption is a function of household income and household characteristics in terms of the number and age of its members.

32. Three sources of demand for investment goods are identified: household; government; and enterprises. Demand for investment from household and government is assumed to respond to such demographic factors as number of households, urbanization and population growth. All sources of investment respond to the usual economic variables, such as household income, growth rate of gross domestic product. In turn, a link is assumed between investment demand and capital formation by sector which appears in the final demand.

33. Government consumption is a function of growth in government revenues, growth in total population and growth in the urban proportion of population.

34. Exports from each production sector are assumed to grow at various constant exogenous rates.

<sup>2</sup> Investment is a function of value-added in the previous period. Since the economic subsystem is essentially an input-output model, this relationship is demand-oriented. Increase in demand for investment is always supplied. To ensure that investment shall be sufficient to generate the increase in output, supply constraints are built in. The supply constraints are sectoral incremental capital-output ratios. Increase in sectoral production or output is matched with the increment in capacity. A convergence to the condition of output equals capacity is obtained by adjustments on final demand. The final demand vector is reduced when there is no excess capacity and vice versa.

<sup>3</sup> Traditional sectors are defined as those having the ability to absorb surplus labour; see paras. 36-39.

Short-term fluctuations are permitted, resulting from the level of foreign reserves available.

35. Imports are computed as proportions of each vector of final demand and deducted from those vectors to leave final demand for domestic production. These proportions depend upon the availability of foreign exchange reserves.

#### *Output and value added*

36. Output from each sector is calculated by pre-multiplying the net final demand by the inverse input-output matrix. The input-output matrix is assumed to remain constant throughout the simulation. However, as the allocation of final demand changes between modern and traditional sectors producing the same good, this amounts to a change in the aggregate technical coefficients of productive sectors—giving more weight to modern techniques of production. It should be emphasized that this is merely a computational convenience to simulate technical progress.

37. Primary inputs, including intermediate imports, are calculated as proportions of gross output levels. Values added, corresponding to the primary distribution of income to households or personal income, are calculated from gross sector output levels, again by assuming fixed proportions. Lastly, base-period values-added were allocated between rural and urban areas according to the judgement of the research team and its judgement of productivity levels in the sectors between rural and urban areas, and a constraint that employment in rural and urban areas should be equal to the respective labour forces. Over time, rural value-added in the modern sector is assumed to grow at the same rate as value added in modern agriculture, and rural value-added in the traditional sector is assumed to grow at the same rate as value added in traditional agriculture. Value added in modern and traditional urban sectors grows as the residual between total value-added and rural value-added for that sector.

#### *Employment and productivity*

38. Employment in each of the modern sectors is calculated by dividing value added by labour productivity. Growth in labour productivity is a function of labour availability, the average growth of educational level of the working-age population and growth in enterprise investment. If the labour force grows very fast in relation to value added in the modern sector, it is possible for increasing under-employment in traditional activities to occur.

39. Employment in each of the traditional sectors is treated as a fixed proportion of the labour force supplied to the traditional sectors, which is calculated as the difference between total labour force and labour force employed in the modern sectors. The traditional sectors are, therefore, treated as "sponge" sectors capable of absorbing those who cannot find employment in the modern sectors. Hence, there is no unemployment, only under-employment in the model, which

conforms to the "unlimited supplies of labour" or dualistic model of economic development.

#### *Household income distribution*

40. One of the central features of this model is its explicit attempt to estimate changes in the size-distribution of income of households.

41. The main assumption underlying the income-distributing mechanisms of the model is lognormality. For each sector, rural and urban, the distribution of value added to individuals—including both profits and wages—is assumed to be approximately lognormal. In addition, for lack of suitable data, household dependency is assumed to be independent of income, which means that the distribution of value added is directly proportional to the distribution of income to households. This assumption allows a simplified income-distributing mechanism to be evolved.

42. Taking a single household size and a constant number of actives per household, although convenient assumptions, are obviously over-simplifications which need further development. One step that will be easily introduced would be to incorporate a distribution of household sizes, maintaining constant labour force participation ratios. A correlation between household size and household income could also be imposed. Since the incomes of workers other than the household head (particularly of women) will, in general, have a different distribution from that of the head, it is arguable that a more complex distribution of sectoral income to different types of worker should be evolved and related to age/sex-specific participation rates.

43. A serious complication arises when household income originates from more than one sector. It might be possible to establish a sectoral classification to minimize this problem for a point in time, but development over time is likely to shift the sectoral allocation of household actives and so would require continuous reclassification. To take non-wage and wage incomes simultaneously into account may involve another problem.

#### BACHUE-2: PHILIPPINES MODEL

44. Bachue-Philippines is the first application of the Bachue prototype model to a specific country. The economic subsystem to be used in Bachue-Philippines is based on the intersectoral consistency model which is being built under the supervision of Erik Thorbecke, with the help of the Bachue team, to be used in connexion with the ILO comprehensive employment mission to the Philippines.

45. A number of modifications will be introduced in the economic subsystem of Bachue-Philippines, compared with that of Bachue-1. The purpose of these modifications is to increase the operational usefulness of the model and to improve the empirical basis of many of the relationships.

46. The heart of the economic subsystem is the large input-output table which was built by the National Economic Council for 1965, using a 194-sector breakdown. This table is currently being consolidated into a 13-sector breakdown which is to be used in the economic subsystem. The essential feature of the sector classification used in Bachue-Philippines is that it distinguishes not only between productive sectors, but along technological lines, i.e., whether the technique of production is "modern" or "traditional". Thus, a certain number of sectors, such as consumer goods, trade, transport and communication, services and agriculture, are subdivided into a modern and traditional part. The criteria that were used in identifying sectors as traditional or modern are: the ratio of self-employed workers and unpaid family workers to total employment; and the average number of workers per establishment.

47. When the model is used for projections and/or simulation purposes, the system is moved through projected changes in the sectoral final demand components. Thus, this procedure entails a number of important steps:

(a) Sectoral consumption functions have to be estimated from household budget surveys. In general, these consumption functions will be estimated for groups of products which can then be aggregated to correspond to the sector. The form of these consumption functions will have to be such that they take into account not only demographic changes, but changes in income *per capita* and in income distribution;

(b) Sectoral exports will be estimated on the basis of the best information available concerning prospects abroad, likely price and terms of trade trends etc.;

(c) Since all imports in the National Economic Council table are treated as competitive, it will be necessary to measure the requirements for intermediate imports as opposed to truly competitive imports;

(d) Sectoral capital formation will have to be estimated in a way consistent with the investment demand necessary to produce the output. This can be done by using a transformation matrix from investment by sector of origin to sector of destination.

48. After these various components of final demand (consumption, exports, imports and capital formation) have been projected, the next step is to derive the corresponding sectoral gross output and value-added magnitudes using the input-output matrix broken down along modern and traditional lines, as described above. Furthermore, on the basis of a more thorough labour market sub-system, currently being developed, the sectoral employment and income distribution can also be obtained. On the basis of a methodology that has already been tested, the personal income distribution resulting from the sectoral distribution can be mapped. At that stage, it could be determined whether the changes in the composition of output and employment would affect household distribution.

49. It is clear that an important advantage of this type of model is that it can predict, within a consistent framework, the likely changes in the level and composition of both employment and value added and the corresponding income distribution. Since many of the demographic variables are influenced by the latter, it makes it possible to improve upon the tenuous formulation which has characterized many attempts at relating changes in income distribution to some of the demographic variables. It is expected that a first version of the economic subsystem of Bachue-Philippines will be available at the end of 1973.

## ANNEX I

### Bachue-1: economic subsystem

#### Subscripts used

1. Let  $i = 1, 2, \dots, 7$  denotes commodity classes.

For  $i = 1$  Agriculture  
 $i = 2$  Consumer goods

$i = 3$  Capital goods  
 $i = 4$  Construction  
 $i = 5$  Trade  
 $i = 6$  Transport  
 $i = 7$  Services

2. Let  $\alpha = M, T$  denotes a modern-traditional classification of sectors.

$\therefore$  each economic sector could be denoted as  $\alpha_i$ ;  
e.g.,  $M_6$  = modern transportation.

For  $\alpha = M \quad i = 1, 2, \dots, 7$   
 $\alpha = T \quad i = 1, 2, 5$

3. Let  $j = 1, 2, 3, 4$  denotes income classes.

4. Let  $\gamma = U, R$  denotes an urban-rural regional classification.

$\therefore$  household income classes are denoted by  $\gamma_j$ ;  
e.g.,  $U_2$  = urban households in income class 2.

For  $\gamma = U, \quad j = 1, 2, 3, 4$   
 $\gamma = R, \quad j = 1, 2$

5. Let  $\gamma_j$  denote the upper income limit of households in class  $\gamma_j$ , then

$$\frac{\bar{U}_1}{\bar{R}_1} < \frac{\bar{U}_2}{\bar{R}_2} < \frac{\bar{U}_3}{\bar{R}_3} < \frac{\bar{U}_4}{\bar{R}_4}$$

6. Let  $k = 1, 2, \dots, 13$  denotes age cohorts of population, then age group in a region could be denoted by  $\gamma_k$ ;

e.g.,  $P_{\gamma_k}$  = population in region  $\gamma$  (urban or rural) in age group  $k$ .

#### Household consumption

$$C_{i,\gamma_j}(t) = f(Y_{\gamma_j}(t-1), m_{i,\gamma}(t), b_{i,\gamma_j}, \gamma(i)) \quad (1)$$

where  $C_{i,\gamma_j}(t)$  = consumption of good  $i$  by households in class  $\gamma_j$ ;

$Y_{\gamma_j}(t)$  = total disposable income of households in class  $\gamma_j$ ;

$b_{i,\gamma_j}$  = income elasticity of good  $i$  with respect to income class  $\gamma_j$ ;

$m_{i,\gamma}(t)$  = equivalent adults per household in region  $\gamma$ , with respect to commodity  $i$ ;

$\eta_i$  = a measure of economies of scale in consumption of good  $i$ .

$$m_{i,\gamma}(t) = \sum_{k=1}^{13} \theta_{i,k} P_{\gamma_k}(t) / H_{\gamma}(t) \quad (2)$$

where  $P_{\gamma_k}(t)$  = number of heads (females plus males) in region  $\gamma$  in age cohort  $k$ ;

$\theta_{i,k}$  = number of adult equivalents in consumption of good  $i$  per person in age cohort  $k$ ;

$H_{\gamma}(t)$  = number of households in region  $\gamma$ .

$$T_M^c(t) = \sum_{i=1}^7 h_i \left( \sum_{\gamma} \sum_j C_{i,\gamma_j}(t) d_{i,\gamma_j} \right) \quad (3)$$

where  $T_M^c(t)$  = taxes on imported consumption goods;

$d_{i,\gamma_j}$  = proportion of consumption imported (good  $i$ , household  $\gamma_j$ );

$h_i$  = import tax rate on consumption good  $i$ .

$$M^c(t) = \sum_{i=1}^7 (1-h_i) \left( \sum_{\gamma} \sum_j C_{i,\gamma_j}(t) d_{i,\gamma_j} \right) \quad (4)$$

where  $M^c(t)$  = imported consumption goods (at world prices).

$$PC_M(t) = \sum_{\gamma} \sum_j C_{i,\gamma_j}(1-d_{j,\gamma_j}) Z_{i,\gamma_j} \quad (5)$$

where  $PC_M(t)$  = final consumption directed at modern sector  $i$ ;

$Z_{i,\gamma_j}$  = proportion of domestic demand of good  $i$  by household  $\gamma_j$  directed at the modern sector.

Note:  $Z_{i,\gamma_j} = 1$  for  $i = 3, 4, 6, 7$ .

$$PC_T(t) = \sum_{\gamma} \sum_j C_{i,\gamma_j}(1-d_{i,\gamma_j})(1-Z_{i,\gamma_j}) \quad (6)$$

where  $PC_T(t)$  = final consumption directed at the traditional sector  $i$ .

#### Government consumption

Government consumption is determined by the following differential equation:

$$\frac{d \ln GC(t)}{dt} = \frac{d \ln Y_g(t) + f \left( \frac{d \ln (P_u(t)/P(t))}{dt} \right)}{dt} + 0.85 \left( \frac{d \ln P(t)}{dt} \right) + r_{gc} \quad (7)$$

where  $GC(t)$  = government consumption;

$P_u(t)$  = urban population;

$P(t)$  = total population;

$r_{gc}$  = an exogenous (autonomous) growth factor;

$Y_g(t)$  = government income;

$$\therefore GC(t) = GC(0) + \int_0^t \frac{d GC(s)}{ds} ds$$

$$GC_{\alpha_i}(t) = g_{\alpha_i} \cdot GC(t) \quad (8)$$

(a) where  $GC_{\alpha_i}(t)$  is government consumption directed at sector  $\alpha_i$ .

(b)  $GW_{\gamma}(t) = W_{\gamma} GC(t)$

where  $GW_{\gamma}(t)$  is government wages paid in region  $\gamma$ ;

and  $\sum_{\alpha} \sum_i g_{\alpha_i} + \sum_{\gamma} W_{\gamma} = 1$ .

#### Exports

$$\tilde{E}(t) = \sum_{\alpha} \sum_i \tilde{E}_{\alpha_i}(0) e^{r_{\alpha_i}(t)} \quad (9)$$

where  $\tilde{E}_{\alpha_i}(t)$  = export from sector  $\alpha_i$ ;

$r_{\alpha_i}$  = the growth rate of export from sector  $\alpha_i$ .

#### Investments

$$I_h(t) = f \left( \frac{d Y_p(t)}{dt}, \frac{d H(t)}{dt}, Y_p(t), H(t) \right) \quad (10)$$

where  $I_h(t)$  = gross household investments (i.e., dwellings);

$Y_p(t)$  = total disposable income;

$H(t)$  = number of households.

$$I_p(t) = f \left( \frac{d TVA(t)}{dt}, TVA(t) \right) \quad (11)$$

where  $I_p(t)$  = gross private investments (excluding housing);

$TVA(t)$  = total value added.

$$I_p(t) = f\left(\frac{d TVA(t)}{dt}, TVA(t), \frac{d P(t)}{dt}, P(t), r_x\right) \quad (12)$$

where  $I_g(t)$  = gross government investment;

$r_x$  = an exogenous growth factor.

$$M^I(t) = I_p(t) \cdot \theta_p \left(\frac{d \ln X_3}{dt}\right) \cdot (1-\rho_p) + I_g(t) \cdot \theta_g \left(\frac{d \ln X_3}{dt}\right) \quad (13)$$

where  $M^I(t)$  = capital goods imported at world prices;

$\theta_p, \theta_g$  = the proportion of gross investment imported;

$\rho_p$  = import tax-rate on capital goods;

$X_3$  = gross output of the capital goods sector.

$$T_M^I(t) = I_p(t) \cdot \theta_p \left(\frac{d \ln X_3}{dt}\right) \rho_p \quad (14)$$

where  $T_M^I(t)$  = taxes on capital goods imported.

$$I_{p\alpha_i}(t) = I_p(t) \cdot (1 - \theta_p) \left(\frac{d \ln X_3}{dt}\right) \beta_{\alpha_i}$$

$$I_{g\alpha_i}(t) = I_g(t) \cdot (1 - \theta_g) \left(\frac{d \ln X_3}{dt}\right) \gamma_{\alpha_i} \quad (15)$$

where  $\beta_{\alpha_i}, \gamma_{\alpha_i}$  are allocation factors of

$I_p(t)$  and  $I_g(t)$  to various sectors.

Similarly,  $I_{h\alpha_i}(t) = I_h(t) \psi_{\alpha_i}$ .

#### Final demand

$$FD_{\alpha_i}(t) = PC_{\alpha_i}(t) + GC_{\alpha_i}(t) + \tilde{E}_{\alpha_i}(t) + I_{h\alpha_i}(t) + I_{p\alpha_i}(t) + I_{g\alpha_i}(t) \quad (16)$$

where  $FD_{\alpha_i}$  = final demand of sector  $\alpha_i$ .

$$TFD(t) = \sum_{\alpha} \sum_i FD_{\alpha_i}(t) \quad (17)$$

where  $TFD(t)$  = total final demand.

$$\text{Let } F = \begin{pmatrix} FD_{M_1} \\ / \\ \cdot \\ \cdot \\ \cdot \\ FD_{M_7} \\ FD_{T_1} \\ FD_{T_2} \\ FD_{T_5} \end{pmatrix} \quad X = \begin{pmatrix} X_{M_1} \\ / \\ \cdot \\ \cdot \\ \cdot \\ X_{M_7} \\ X_{T_1} \\ X_{T_2} \\ X_{T_5} \end{pmatrix} \quad (18)$$

Then

$$X(t) = (I-A)^{-1} F(t) \quad (19)$$

where  $X(t)$  = vector of gross output;

$F(t)$  = vector of final demand;

$A$  = matrix of technical coefficients.

#### Value added

$$V(t) = \hat{V}X(t) \quad (20)$$

where  $\hat{V}$  = a diagonal matrix of proportions of value added to gross output;

$V(t)$  = the vector of value added.

$$V(t) = V_u(t) + V_r(t) \quad (21)$$

where  $V_\gamma(t)$  is the vector of value added in region  $\gamma$ .

$$\text{Let } V_r(t) = \begin{pmatrix} V_{M_r}(t) \\ V_{T_r}(t) \end{pmatrix} \quad \text{where } M, T \text{ denote modern and traditional sectors respectively.}$$

$$V_{M_r}(t) = \xi_M \cdot V_{M_1}(t)$$

$$V_{T_r}(t) = \xi_T \cdot V_{T_1}(t) \quad (22)$$

where  $\xi_M, \xi_T$  are vectors of proportions determined at  $t = 0$ ;

$$\text{e.g., } \xi_M = \begin{pmatrix} V_{M_1}(0)/V_{M_1}(0) \\ V_{M_2}(0)/V_{M_1}(0) \\ \cdot \\ \cdot \\ V_{M_7}(0)/V_{M_1}(0) \end{pmatrix}$$

$$\xi_T = \begin{pmatrix} V_{T_1}(0) \\ V_{T_2}(0) \\ V_{T_5}(0) \end{pmatrix} \frac{1}{V_{T_2}(0)}$$

$$VA_\gamma(t) = \sum_i \sum_{\alpha} V_{\alpha_i}(t) + GW_\gamma \quad (23)$$

where  $VA_\gamma(t)$  = value added in region  $\gamma$ ;

$GW_\gamma$  = government wages paid in region  $\gamma$ .

$$D(t) = \omega'X(t) \quad (24)$$

where  $D(t)$  = capital depreciation;

$\omega$  = vector of depreciation rates.

$$T_{id}(t) = \tau'X(t) \quad (25)$$

where  $T_{id}(t)$  is total indirect taxes on sectors;

$\tau$  = vector of indirect tax rates.

$$M^{IN}(t) = (1-s_{IN}) \phi' X(t) \quad (26)$$

where  $M^{IN}(t)$  is imports of intermediate inputs at world prices;

$s_{IN}$  is the import tax rate on intermediate inputs;

$\phi$  = vector of import coefficients.

$$IN_{\gamma}(t) = \psi' X(t) \quad (27)$$

where  $IN_{\gamma}$  is input of government output into sectors.

$$TVA(t) = \sum_{\gamma} VA_{\gamma}(t) + D(t) \quad (28)$$

$$T_{IN}(t) = s_{IN} \phi' X(t) \quad (29)$$

where  $T_{IN}(t)$  is import taxes on intermediate inputs.

#### Employment (modern) sectors

Let  $E_{\alpha_i, \gamma}$  denote employment in sector  $\alpha_i$  in region  $\gamma$ , then:

$$E_{M_i, \gamma}(t) = \frac{V_{M_i, \gamma}(t)}{l_{M_i, \gamma}(t)} \quad \begin{matrix} i = 1 \dots 7 \\ \gamma = u, r \end{matrix} \quad (30)$$

where  $l_{M_i, \gamma}(t)$  denotes labour productivity;

$$E_{g, \gamma}(t) = \frac{GW_{\gamma}(t)}{l_{g, \gamma}(t)}$$

where  $E_{g, \gamma}(t)$  = government employment in region  $\gamma$ ;

$l_{g, \gamma}(t)$  = labour productivity in government.

$$E_{M, \gamma}(t) = \sum_{i=1}^7 E_{M_i, \gamma}(t) + E_{g, \gamma} \quad (31)$$

where  $E_{M, \gamma}$  denotes modern employment in region  $\gamma$ .

#### Productivities

$$l_{M_i, \gamma}(t) = f(r_{M_i, \gamma}, L_{\gamma} - E_{M, \gamma}(t), K_p(t)) \quad (32)$$

where  $r_{M_i, \gamma}$  = rate of technical progress in sector  $M_i$  in region  $\gamma$ ;

$L_{\gamma}$  = labour force in region  $\gamma$ .

Similarly,

$$l_{g, \gamma}(t) = f(r_{g, \gamma}, L_{\gamma} - E_{M, \gamma}(t))$$

where  $r_{g, \gamma}$  is rate of technical progress in government production.

#### Employment (traditional) sectors

$$E_{T, \gamma} = L_{\gamma}(t) - E_{M, \gamma}(t) \quad (33)$$

where  $E_{T, \gamma}$  is employment in traditional sectors in region  $\gamma$ .

$$E_{T_i, \gamma}(t) = \phi_i E_{T, \gamma}(t) \quad (34)$$

where  $\phi_i$  = a constant determined at  $t = 0$ ,

such that  $\sum_i \phi_i = 1$

$$l_{T_i, \gamma}(t) = \frac{V_{T_i, \gamma}(t)}{E_{T_i, \gamma}(t)} \quad (35)$$

$$E_{\gamma}(t) = \sum_{\alpha} \sum_i E_{\alpha_i, \gamma}(t) \quad (36)$$

$$E(t) = \sum_{\gamma} E_{\gamma}(t) \quad (37)$$

where  $E(t)$  is total employment.

#### Income

Let  $\bar{Y}_{\gamma_j}$  denote total income of households in class  $\gamma_j$  before taxes, then:

$$T_p(t) = \sum_j \sum_{\gamma} \bar{Y}_{\gamma_j} \cdot t_{p, \gamma_j} \quad (38)$$

where  $T_p(t)$  is personal taxes;

$t_{p, j}$  are tax rates.

$$Y_{\gamma_j} = \bar{Y}_{\gamma_j} (1 - t_{p, \gamma_j}) \quad (39)$$

where  $Y_{\gamma_j}$  = disposable income.

$$Y_p = \sum_{\gamma} \sum_j Y_{\gamma_j} \quad (40)$$

where  $Y_p$  = total disposable income.

$$S_{\gamma_j} = Y_{\gamma_j} - \sum_{i=1}^7 C_{i, \gamma_j} \quad (41)$$

where  $S_{\gamma_j}$  is personal savings of households in class  $\gamma_j$ .

$$S_p(t) = \sum_{\gamma, j} S_{\gamma_j} + D(t) \quad (42)$$

where  $S_p(t)$  is personal savings.

$$S_g(t) = \left( \sum_{\gamma, j} \bar{Y}_{\gamma_j} \cdot t_{p, \gamma_j} \right) + T_M^C(t) + T_{id}(t) + IN_g(t) + T_M^{IN}(t) - GC(t) \quad (43)$$

where  $S_g(t)$  is government savings.

$$B(t) = \tilde{E}(t) - M^C(t) - M^I(t) - M^{IN}(t) \quad (44)$$

where  $B(t)$  = balance of payments;

$$INGAP(t) = I_H(t) + I_p(t) + I_g(t) + B(t) - S_g(t) - S_p(t)$$

where  $INGAP(t)$  is a check on computational error.

$$\text{Log } W_{\alpha_i, \gamma}(t) \sim N(\tilde{1}_{\alpha_i, \gamma}(t), \sigma^2_{\alpha_i, \gamma}(t)) \quad (45)$$

where  $W_{\alpha_i, \gamma}(t)$  = payment of wages and profits in sector  $\alpha_i$  in region  $\gamma$ ;

$\tilde{1}_{\alpha_i, \gamma}(t)$  = mean of the normal distribution of  $1_{\alpha_i}$  in region  $\gamma$

where  $\tilde{1}_{\alpha_i, \gamma}(t) = \ln 1_{\alpha_i, \gamma}(t) - 1/2 \sigma^2_{\alpha_i, \gamma}(t)$

$1_{\alpha_i, \gamma}(t)$  = productivity for sector  $\alpha_i$  in region  $\gamma$ .

$\sigma_{\alpha_i, \gamma}(t)$  = standard deviation of the normal distribution

where:

$$\sigma_{\alpha_i, \gamma}(t) = k_{\alpha_i, \gamma} [\ln 1_{\alpha_i, \gamma}(t)]$$

$k_{\alpha_i, \gamma}$  = a constant.

Household income distribution is derived from personal income distribution by assuming constant number of actives per household. The implicit assumption is that workers in the same household are in the same earnings groups. Hence,  $H_{\gamma_j}(t)$ , number of households in income class  $\gamma_j$ , can be derived as follows:

$$H_{\gamma_j}(t) =$$

$$\frac{1}{A_\gamma} \left[ \sum_i \sum_\alpha E_{\alpha_i, \gamma}(t) \int_{\bar{\gamma}_{j-1}/A_\gamma}^{\bar{\gamma}_j/A_\gamma} d\Lambda(\bar{1}_{\alpha_i, \gamma}(t), \sigma^2_{\alpha_i, \gamma}, W_{\alpha_i, \gamma}) \right. \\ \left. + E_{g, \gamma}(t) \int_{\bar{\gamma}_{j-1}/A_\gamma}^{\bar{\gamma}_j/A_\gamma} d\Lambda(\bar{1}_{g, \gamma}(t), \sigma^2_{g, \gamma}(t), W_{g, \gamma}) \right]$$

$$\gamma = U, R$$

$$j = 1, 2, \text{ for } \gamma = R$$

$$j = 1, 2, 3, 4, \text{ for } \gamma = U$$

where  $A_\gamma$  = number of actives per household in region  $\gamma$ ;  
 $\bar{\gamma}_{(k-1)}, \bar{\gamma}_k$  = lower- and upper-income limit of household income in class  $\gamma_j$ .

Total income in class  $\gamma_j$ , denoted by  $\tilde{Y}_{\gamma_j}$  can be calculated as:

$$\tilde{Y}_{\gamma_j}(t) =$$

$$\sum_i \sum_\alpha E_{\alpha_i, \gamma}(t) \int_{\bar{\gamma}_{j-1}/A_\gamma}^{\bar{\gamma}_j/A_\gamma} W_{\alpha_i, \gamma} d\Lambda(\bar{1}_{\alpha_i, \gamma}(t), \sigma^2_{\alpha_i, \gamma}(t), W_{\alpha_i, \gamma}) \\ + E_{g, \gamma}(t) \int_{\bar{\gamma}_{j-1}/A_\gamma}^{\bar{\gamma}_j/A_\gamma} W_{g, \gamma} d\Lambda(\bar{1}_{g, \gamma}(t), \sigma^2_{g, \gamma}(t), W_{g, \gamma})$$

## POPULATION, ENVIRONMENT AND NATURAL RESOURCES: A CRITICAL REVIEW OF RECENT MODELS \*

*Nicholas Carter \*\**

1. In the past decade, the world has seen several new waves of Malthusian predictions. What makes the most recent crest different from previous ones is the use of mathematical models and the computer. These two modern tools, regarded by laymen as somehow having special powers, plus the publicity arising from their use, have produced what is popularly known as the "Doomsday Model". The popular message of this type of model is simple and Malthusian: mankind is currently outgrowing the capacity of the planet to support it and thus will experience future disasters with falling levels of material welfare and falling numbers of people in the world unless there are profound changes in the nature of current technologies and values. Some of the more extreme predictions suggest that because of the long delays inherent in mankind's corrective mechanisms, there is no way to avoid such disasters; others prescribe zero population growth and zero material growth as a means of avoiding catastrophe. These predictions have come from developed countries, where growing discontent with current trends and values provides a sympathetic audience for such predictions. The models' message, in the context of those countries, is to stop growing in order to maintain or reduce current levels of living while reducing sharply the material content of such levels. The focus of these discussions is "the American way of life" or its counterpart in other developed countries, and the prescriptions are basically oriented in that direction. Little is actually said about the developing countries of the world other than the ever-popular words of wisdom, "don't populate". The practical implications of the prescriptions are quite ominous for the developing countries; no growth in the material level of living, combined with a very long lag in any practical reduction of population, easily produces for them the Malthusian result, while, at the same time, it is predicted that the developed countries would be able to survive with far less drastic problems. This is certainly not an acceptable outlook for the world community of nations.

2. It is thus very important to look closely at the basis for these predictions and the models involved. Moreover, when one looks more carefully at the field

of population and resource analysis one discovers a number of well thought-out studies that are worth serious attention, if only in a comparative sense, but which, unfortunately, have not been given much attention. Lastly, one finds that in response to the message of the "doomsday" models, several attempts have been made to redefine objectives and to work out future scenarios that will meet both the resource limitations and, at the same time, satisfy objectives of providing all mankind with at least certain minimum levels of welfare.

3. This paper takes a critical look at world models (most of the doomsday models fall into this category), at the more conventional population and resource analyses and at the attempts to work out suitable alternatives. The paper does not pretend to be exhaustive. There are a large number of existing models; the selection has been based upon their intrinsic interest, the publicity that they have gained and their availability to the author. The common characteristics of all the selected models are that the time span is at least to the year 2000, and usually beyond and that there is a population projection which is linked to the economy and/or resource requirements in either direction. Thus, purely demographic projection models, purely economic models and short-run models are omitted.

4. A common model begins with a projection of population, as a rule for a period of about 50 years. Given the nature of population dynamics and the fact that the time constant for human populations (that is, the time it takes for a given demographic change to work itself through the population) is on the order of 70 years, it is fairly easy to make such a projection; and given the nature of uncertainty in long-term projections, the forecast of population is by far the most accurate element in any model. The next step is to link these population projections to demands on resources (in varying degrees of aggregation) or to such macro-economic variables as consumption and investment, and thus the growth of output. Lastly, in the more innovative cases, the projections of material levels of living are connected back to such demographic variables as birth and death rates, thus completing the cycle. The more conventional of these models study the interactions in both directions and try to predict the magnitudes of the future on this basis, while the world models add resource constraints, which, in turn, usually prevent the

\*\* Chief, Comparative Analysis Projection Division, International Bank for Reconstruction and Development.

orderly growth of the system, and thus conclude either that the future projection must be drastically modified, or that there must be immediate and significant changes in policy that will modify the interactions of population and resources.

5. A feature often present in both types of models is a consideration of environment. The environmental dimension is much more difficult and has thus far proved to be a serious, but not critical, element in the consideration of the future; i.e., in some runs of the doom models pollution is the cause of disaster; but with relatively small changes in policy such scenarios can be avoided.<sup>1</sup>

6. It should be made clear that this paper is an attempt to look at different types of models. Their common characteristics are the links between population, resources and (sometimes) environment. It is not intended that the models in their entirety be compared directly with one another. Clearly, they are designed for different purposes; each is judged more on how it answers the questions it was designed to address and on how it represents the population-resource-environment nexus. World models (or doom models) address the global problems of mankind. Their weaknesses seem to arise from chronic under-specification. Conventional models look at countries or sectors. These models, also, are usually under-specified and they implicitly assume the rest of the world to be infinite and unchanged. This latter fault, perhaps, limits their usefulness in the long run, but certainly does not rule them out as guides for medium-run policy action.

7. Running through many models, in particular the more celebrated ones, one finds the theme of systems dynamics, which is an innovative tool enabling one to have insights into the workings of systems that would not be possible with conventional methods. Its great success has been with micro-systems where, as long as the system was correctly and completely specified, it has proved far more incisive and encompassing than conventional tools. Its efficacy on macro-systems, where specification is, by necessity, incomplete, is still very much a matter of debate. A great deal is made of the counter-intuitive nature of systems and thus the necessity of using systems dynamics. It is basically a simulation method, not radically different from conventional projection model systems. It is extremely flexible and much easier to use than most, but when used for macro-systems suffers more than usual from the problems that plague all simulations. In most micro-systems it is fairly easy to agree on an exact specification, to model each interaction and even in some cases to verify by experiment. In macro-systems such is not the case. Rarely, if ever, is there agreement with regard to the correct specification of the system. Computer space does not

<sup>1</sup> Based on experiments conducted on the World 3 model (the "Limits to Growth" model) by the author of the present paper. See Donella H. Meadows and others, *The Limits to Growth: A Report for the Club of Rome's Project on the Predicament of Mankind* (New York, Universe Books, 1972).

allow an exhaustive specification, and attempts in this direction have thus far proved to be intractable. Verification experiments almost never can be carried out, and it has proved almost impossible to avoid an incorporation of subjective bias into macro-models. Perhaps most important, primarily because of chronic under-specification, a multitude of models can all be equally "proved" using accepted measurement techniques on the same body of data. Systems dynamics and its associated computer tools make it extremely easy to build a model and thus to "discover" a fundamental truth, which, in reality, arises from a misspecification.<sup>2</sup> Properly used, however, it can be a powerful analytical tool.

8. This paper examines 11 models relating to population. Of these, three fall into the world model category: "World Dynamics";<sup>3</sup> "Limits to Growth";<sup>4</sup> and "Models of Doom".<sup>5</sup> Six models may be classified as conventional: the Coale-Hoover model;<sup>6</sup> the TEMPO model;<sup>7</sup> the Bachue model;<sup>8</sup> the Bangladesh model;<sup>9</sup> the United States Population Commission model;<sup>10</sup> and the model created for the Government of Mexico by the International Bank for Reconstruction and Development (IBRD-Mexico).<sup>11</sup> The Coale-Hoover model is included, not because it is recent, but because it was the first serious attempt in modern times to deal with the connexion between population and resources and, as such, many other models are descended from it. Lastly, two additional models are considered which represent attempts to reformulate the objectives of growth and development and to build future models upon this foundation: the Latin American World Trade Model<sup>12</sup> and the Japanese World Model.<sup>13</sup> These

<sup>2</sup> It is the opinion of this author that some (by no means all) of the more spectacular findings of the "Limits to Growth" model have arisen from these types of phenomena rather than from fundamental characteristics of the human race.

models are particularly important because they begin with the implied doom model message that the Western way of life is probably no longer viable and they seek to discover if some other way of life is perhaps more viable. There are, of course, other groups engaged in similar work, but the non-Western attempts have been chosen as being potentially more representative for mankind as a whole.

9. Not discussed in this paper, but worthy of mention, are the efforts of several other groups. In the Netherlands, under the direction of Tinbergen and Linnemann, work is under way on the agricultural section of a world model. At Case Western Reserve University (Cleveland, Ohio) under Mesarović, and at Hannover under Pestel, an "alternative world model system" is being created which appears to have great promise. Lastly, at Harvard under Leontieff, a world model system is being built from a series of input-output systems. Its basic structure is similar to that of the model used by the United States Commission on Population Growth and the American Future.

#### WORLD DYNAMICS

10. The model in the book, *World Dynamics* (technically termed "World 2"), produced in 1970, was developed by Jay W. Forrester of the Massachusetts Institute of Technology (MIT) and later was adopted by the Club of Rome. As such, it is the first world model and represents a good, but hasty, look at the over-all problem of the relation of population, resources and environment in the context of the entire world. Its value lies in the fact that it called attention to the possibility of a conflict between the continued growth of the world population and the world economy on the one hand, and the limitations of resources and of absorption of waste, on the other.

11. The model consists of four key variables: population; natural resources; capital stock; and pollution (this variable, in all the world models does not refer to short-lived pollution, such as smog, but rather to the long-lived pollutants, such as DDT and mercury). Each of the four variables is related to the others through behavioural relationships. A fifth variable, capital investment in agriculture, determines the amount of food available to the world. There are a large number of intuitively specified links between the five variables, most of which have little or no effect on the workings of the model, unless certain extreme assumptions are made to activate them.<sup>14</sup> In the standard run of this model, population increases gradually until it reaches a level somewhat over 5 thousand million in the year 2020, after which it declines at about the same rate. The material level of living, which essentially reflects the *per capita* availability of fixed capital, rises until about

1990 and then falls fairly smoothly. The population growth rate is determined chiefly by this material level of living and also by the density of population (termed "crowding"). Since the growth of population is simply the difference between the birth and death rates, the key relationships are the effects of material levels of living and crowding on these rates. According to the assumptions of the model, the death rate is much more sensitive to these variables than is the birth rate, being pushed up from the normal of 28 per 1,000 to the mid-1930s by crowding, and then to the mid-1940s by a falling material level of living. At the same time, the birth rate drops slightly from the normal 40 and then rises as levels of living fall. The two other variables affecting the birth and death rates are food and pollution; these have a potential for making significant shifts, but, in the normal extrapolation of current trends, play little or no part.

12. In World 2 one clearly sees the effect of crowding and material well being on demographic rates. These, however, are very simplistic relationships and have been criticized as such, particularly on the grounds of non-reversibility. As specified, the functions work in both directions, that is, as material levels of living and crowding rise and fall, even though the observations available to the model-builder were only for rising trends. This implies that as incomes go up, birth rates will fall, a phenomenon that is reasonably well documented; while at the same time, if incomes fall, birth rates will immediately go up again, a proposition which does not appear reasonable. Similarly, while crowding acts weakly to lower birth rates, it does not follow that an absence of crowding will raise them. Moreover, while the effect of crowding on death rates may have been evident in the days of the Black Death, it does not follow that such would now be the case and that uncrowding would reduce the death rate; nor does it follow that whatever the effect of crowding on demographic variables is, that the effect is independent of levels of income.

13. Thus, while the effects of economic and social variables on population may have been taken into account in the model, though in rudimentary fashion, one cannot treat the results as definitive predictions. Far more work must be done, as, indeed, the author freely admits.

14. The question may be asked, with respect to opposite interactions, what the effects of population levels are on economic and social variables. The key variables in this part of the model are natural resources and capital stock, which determine the material level of living, which, as has been seen, affects the demographic variables of the model. Natural resources are given to the system in a fixed amount at the beginning of the model and are steadily used up by the process of creating capital stock. Capital stock grows according to the difference between the rate of investment and the rate of depreciation. In the initial stages of the model, this growth rate is about 0.4 per cent per annum and

<sup>14</sup> Statements concerning the way in which the Forrester model (World 2) and the "Limits to Growth" model (World 3) work have been derived from the author's own fairly exhaustive testing of the actual computer models involved.

it falls steadily as natural resources are used up, until ultimately it reaches the limit of —2.5 per cent, which is the constant rate of depreciation. No matter what assumptions are made, natural resources eventually run out and the system stops growing.

15. There are many apparent links from the population section to the capital investment and natural resources parts of the model; but in actual model practice, these links are either self-cancelling, or negligible.<sup>15</sup> The speed of the rise and fall of the "world system" depends almost exclusively upon the amount of natural resources remaining and the level of capital investment. This latter relationship is set up so as to increase the rate of resource usage as the capital stock grows. While this may be a plausible aggregate representation (one of many possible) of past secular trends, it rules out the feasibility of policy changes in the model designed to "save" the system. The problem is neither the model nor the intrinsic nature of the world, but that the relationship is an under-specified aggregate. For example, an increase in the productivity of capital would be expected to reduce the investment rate and, thus, the usage of resources. In the World 2 model, such a change increases the effective capital and, thus, the level of living and, thus, the usage of resources. Moreover, the higher the level of capital stock, the greater the level of pollution, so that any attempts to get more production from a given amount of resources or, for that matter, to increase the amount of resources, produce "pollution crises" which themselves bring on the collapse. Therefore, it does no good, in the context of the World 2 model to increase the natural resources available either in a lump amount or on a gradual basis; collapse cannot be avoided. The fact that an increase of resources or a rise in the productivity of capital still brings collapse, and in some cases more rapidly, is cited by J. W. Forrester as an example of the "counterintuitive nature of social systems".<sup>16</sup> It is suggested that it may be a case where the model-builder has failed to understand and specify in sufficient detail the real workings of particular subsystems, particularly that of capital.

16. Thus, one has the World Model in which there is a link from resources to population that operates partially, but not entirely, satisfactorily and a link from population to resources that is virtually non-existent. The model indicates a high probability of collapse, not because this is the way the world necessarily behaves, but because of the particular manner in which the model was specified.

#### THE "LIMITS TO GROWTH" MODEL

17. J. W. Forrester recognized many of the shortcomings of his model and urged continued research

<sup>15</sup> The author has fairly exhaustively tested the World Dynamics model, and the description of the way in which the model works is derived from these tests.

<sup>16</sup> Jay W. Forrester, "Counterintuitive behavior of social systems", *Technology Review*, vol. 73, No. 3 (January 1971), pp. 52-68. One wonders how much of this counterintuitive

into the problem. While many critics were loudly pointing out the flaws in the model (and some criticism was frankly emotional rather than scientific) a group of Forrester's students at MIT (under the leadership of Dennis Meadows) began to modify and improve the original World 2 model. This group produced a model, called "World 3", the results of which were published in 1972 in *The Limits to Growth*.<sup>17</sup> Whereas *World Dynamics* presented a discussion of the problem and the conclusions, as well as a completely documented version of the World 2 model, *The Limits to Growth* contains only the conclusions from the World 3 model and, through no fault of the Meadows group, was presented to the world in a spate of popular publicity. The clear message of doom (at least for the "American way of life") was ascribed to the work, and the obvious suggestions of critics (such as resource cornucopia) were answered with computer runs "showing" that such advice was not of any benefit to the world.<sup>18</sup> While World 3 and its technical background<sup>19</sup> have always been available from the group at the Massachusetts Institute of Technology, formal publication was scheduled to occur more than two years after *The Limits to Growth*, a delay that is perhaps inconsonant with the immense publicity given to the book. This situation is, perhaps, unfortunate for the model and for all population-resource models in general, for as the group began to make the model itself available to a few researchers, it became evident that the World 3 model was in need of more work and that the sensational conclusions ascribed to it were for the most part unjustified. Having been prematurely over-publicized, it will be difficult in the future for this or any other serious piece of work with similar pessimistic conclusions to get the serious attention it deserves.

18. In World 3, as in World 2, the central parts of the model are the population subsystem and the capital stock-natural resources subsystem. There are other state variables, such as pollution, service capital and land; but, in general, these variables play the same minor roles as they did in World 2.<sup>20</sup> The general nature of the model is the same. The population system has weak inputs from the capital and resources system; but the equation links from population to capital and resources, although existent, virtually cancel out the effects of these variables. There is, thus, an essentially self-generated capital stock whose growth is determined by the parameters chosen for it and whose end comes

behaviour is simply a re-expression of the familiar "fallacy of composition".

<sup>17</sup> Donella H. Meadows and others, *op. cit.*

<sup>18</sup> *Ibid.*, see especially chap. IV.

<sup>19</sup> Donella H. Meadows and others, *The Dynamics of Growth in a Finite World* (to be published). This is the technical report to *The Limits to Growth* and has gone through at least three versions and countless extensions of the publication date. At this writing, the publication is scheduled for mid-1974, more than two years after publication of *The Limits to Growth*.

<sup>20</sup> The author has fairly exhaustively tested the "Limits to Growth" model and the description of the way in which the model works is derived from these tests.

when natural resources are so depleted as to require the diversion of capital to resource extraction rather than to making new capital. Eventual collapse has thus been built in, regardless of what happens to the rest of the model.<sup>21</sup>

19. The population subsystem of the model World 3 has considerably more detail than did World 2. In itself, it is fairly well constructed, using four cohorts in the standard version and 15 in a more detailed version. Each cohort has its own demographic parameters and the over-all system is probably as good as most in terms of the prediction of over-all population size up to 50 years in the future. The links from the rest of the model to the population subsystem are, for the most part, non-functioning in standard runs of the model. Births are regulated through a variable called "total fertility", while deaths are controlled by life expectancy. Fertility is specified to be determined by social and industrial output *per capita*, and by life expectancy. What turns out to have virtually all the effect in the actual running of the model is the change in the level of income.<sup>22</sup> This change is scarcely more than the classical relationship between the birth rate and income; and, as in World 2, the model-builders treat it as a reversible relationship.<sup>23</sup> With deaths the situation is similar. Life expectancy is modeled to be determined by pollution, crowding, availability of health service and availability of food. In the actual running of the model, the largest impact comes from crowding (although in the early part of the model there is a one-time decrease in the death rate caused by the general improvement of health in the 1930s). The crowding multiplier is a function both of population density and also of income level, the latter being capable of changing rapidly, the former very slowly. The authors reasoned that plagues result from crowding at low income levels; and thus, as income falls because the world runs out of resources,<sup>24</sup> a "Black Death" hits the population of World 3. This is as close to disaster as either World 3 or World 2 gets; and it is built in, one suspects, as the result of reversibility of the model rather than on purpose. Again, one has the situation of a population system that is internally well defined, but whose links to the rest of the model need strengthening.

20. In the capital section, however, even the internal mechanics are in need of repair. This is the key sector of the model, the one that is primarily responsible for the familiar over-shoot and collapse which has given rise to so much controversy.

21. When looking at the capital sector, one is immediately struck by its "counter-intuitive" behaviour. In one experiment an attempt is made to prolong the collapse by increasing the productivity of capital. Intuition says that such an increase (through the lowering of incremental capital/output ratio (ICOR) should give more output for a given amount of capital and thus be less intensive in the usage of non-renewable natural resources, thereby prolonging the time for which such resources can be used. The model, however, gives the opposite result; instead of a collapse in year 120, industrial output begins to fall sharply after only 70 years. The authors then go on to imply that this is an argument for not varying this constant in the policy simulations, on the grounds that the model is too sensitive to ICOR,<sup>25</sup> but the counter-argument might also be made that this is a good reason to examine closely the reasons why the model so behaves. Moreover, if one is "counter-intuitive" and increases ICOR (thus lowering the productivity of capital), the model gives the world an extra 50 years before collapse.<sup>26</sup> One could say the model is counter-intuitive, but "Occam's razor" would suggest that the capital sector may not have been specified correctly.

22. In the capital sector of World 3, industrial capital is assumed to be the source of all capital goods and of a sizable fraction of consumer goods. Thus, unless there is industrial capital, the model can only function at a primitive, peasant society level where everything that is produced is food and services. (Even here the model is not clear, as it requires \$40 of capital *per capita* to produce services even when industrial output is zero. A better definition, perhaps, of the services sector would be to allow this subsistence level of services to be produced without capital.) Industrial capital in the model is generated on a residual basis from industrial output, which itself is generated from industrial capital. This very tight loop is interrupted only by the need to supply capital to other sectors and the need to use capital to extract natural resources and depreciation, and continues so long as there are natural resources still available. The main parameters that determine the dynamic characteristics of this loop are ICOR, the lifetime of capital (ALIC) and the fraction of capital necessary to obtain resources (FCAOR).

$$\frac{d(IC)}{IC} = \frac{A(1 - FCAOR)}{ICOR} - \frac{1}{ALIC}$$

where *IC* is industrial capital.

The parameter *A* contains two variables that, in practice, are slightly sensitive to population, but, in general, move only after a collapse.<sup>27</sup> In a normal run, the value of this equation is about 4.5 per cent per annum.

<sup>21</sup> Except, of course, in the extreme case of infinite resources, where pollution and/or agricultural-land scarcity produce the collapse.

<sup>22</sup> This conclusion is derived from the author's fairly exhaustive tests of the "Limits to Growth" model.

<sup>23</sup> The key variable seems to be "desired total fertility" (DTF) and most of its variation comes from "industrial output *per capita*" (IOPC) by way of a delay system. See Donnella H. Meadows and others, *The Dynamics of Growth in a Finite World*, *op. cit.*, chap. II, equations 122, 127 and 128, and fig. II-49.

<sup>24</sup> *Ibid.*, chap. II, fig. II-39.

<sup>25</sup> *Ibid.*, p. VII-24 and fig. VII-10.

<sup>26</sup> This conclusion is derived from the author's fairly exhaustive tests of the "Limits to Growth" model.

<sup>27</sup> Donnella H. Meadows and others, *The Dynamics of Growth in a Finite World*, *op. cit.*, p. III-78; also experiments by the author of this paper.

23. Looking briefly at the formulation of FCAOR, the natural resources limitation, it is a function of natural resources remaining in the system. This function is such that FCAOR is 0.05 until the natural resources reach 50 per cent of their original level, at which point it jumps to 0.10 and then rapidly to 0.70 as the fraction remaining drops to 20 per cent, ultimately reaching 1.0 when natural resources are at 0 per cent of their original level. Critics have argued about the rapidity of growth of costs (especially since they have, in general, fallen over the past 70 years); and the concept that it is industrial capital that must be diverted in order to obtain natural resources. The usage rate of natural resources is the product of population (the more people you have, the faster you use resources) and the usage rate *per capita*. The latter is a rising function of industrial output *per capita*, which tends to taper off at high levels of income. The result is a steady depletion which is accelerated by an increase in population or level of living, with only very weak provisions for slowing down and no provisions for replenishment of any kind. Under this kind of formulation, a collapse result is inevitable. Note that this is the only link between population and the capital and resources systems. The model does not consider consumption, prices,<sup>28</sup> consumer utility or any of the many linkages that modern economics would suggest as having an effect in determining capital formation and resource use. All World 3 has is a steady drain on resources; which is determined by how many people there are and how rich they are. Since changing the size of the population is a long-run question and the amount of resources given to World 3 is fixed and relatively small, it is difficult to avoid a conclusion of doom.

24. Consider now two suggestions of model critics, the lowering of ICOR and the increasing of the lifetime of capital. Suppose ICOR were 2.0 (instead of 3), then the growth of capital, by the above-mentioned formulation, jumps to 11.3 per cent. Similarly, if ALIC were 20 instead of 14, the rate of growth of IC would be 7.3 per cent. Both cause faster growth and both thus bring the system into a more rapid collapse. Even assuming an infinite supply of natural resources, this formulation leaves something to be desired.

25. The key problem here is that of the industrial capital investment rate. As defined in World 3, it is a residual and only changes because some other demand for industrial output changes. There are no direct links with the depreciation rate, and this aspect gives the system its counter-intuitive behaviour. There are no links with population or its growth rate, nor are there any links with demand or expectations of demand. The investment function simply says that the system invests whatever is left over, no matter how large or small and no matter how related this supply is to the needs of the system. This is an archaic form of the investment

function, similar to the "investible surplus" idea. But the investible surplus theory relates to subsistence economies and refers to agricultural, not industrial, output. Moreover, even if one subscribed to the idea that the investors of the world are motivated to invest whatever they can get their hands on, the behaviour would have to be modified somewhat by calculations of short-run profit, which itself has to be related to the demand of the system.

26. To be fair, there are a number of "equilibrium" runs shown in both *The Limits to Growth* and *The Dynamics of Growth in a Finite World*. These runs imply a number of extremely difficult direct and immediate policy choices to be made by the leaders of the world if the model is correct and if the world wishes to arrive at some kind of non-collapse equilibrium. Moreover, it is highly unlikely that such choices would be made in time even if everyone accepted the conclusions of World 3 as gospel. Therefore, both World 2 and World 3 must be implicitly regarded as doomsday models.

#### MODELS OF DOOM

27. One of the groups to whom a copy of *The Dynamics of Growth in a Finite World* was made available was the Science Policy Research Unit at the University of Sussex. They made a careful analysis of the World 3 model, criticized each parameter in detail and formulated a number of modifications of their own. Early in 1973, they published a book of their findings under the title *Models of Doom*.<sup>29</sup> The work is recommended for understanding in detail both the philosophy and the mechanics of *The Limits to Growth*.<sup>30</sup> It is considered briefly because it has made a number of modifications to the model in an attempt to make the model more realistic. These modifications are, in general, those which have occurred to most critics: increasing the amount of resources, lowering the sensitivity to pollution, changing the productivity of agriculture etc. No structural changes have been made, however, to the key sectors of population and capital or to the links between them. Its primary purpose is a critique, and, as such, it works within the framework of the models it criticizes.

28. This paper has dwelt at length on world models because they have received a large amount of publicity, and because they have, in general, made their detailed specifications available to interested researchers. The general conclusion is that, although they call attention to a potentially serious problem for the world as a whole, as models they have significant short-comings. A series of more conventional models that look at the interactions between population and resources is now considered. These models do not try to predict the future of mankind, but they do permit forecasts to be made of possible future behaviour, particularly in the shorter run. As discussed above, they should not be

<sup>28</sup> Specifically, if prices rise, demand should fall. World 3 implicitly assumes demand *per capita* to be fixed and thus equilibrates the system by increasing costs.

<sup>29</sup> H. S. D. Cole, *op. cit.*

<sup>30</sup> *Ibid.* See, in particular, chap. 2.

compared with the world models, but rather looked at in terms of their specifications.

#### COALE-HOOVER MODEL

29. The Coale-Hoover model is included because it was essentially the first to look at the links between demographic trends and the workings of a national economy. Published in 1958, the model argued that economic growth is critically dependent upon investment, and thus upon savings, and that savings is affected by the fertility of the population.<sup>31</sup> Fertility is taken to be independent of changes in the level of economic well-being, or at least not within the framework of the model. The model, therefore, focuses on the linkage from population to the economy, the two main sectors themselves being conventionally<sup>32</sup> defined. The key linkage is through savings and investment. The savings equation is defined so as to produce higher rates of saving at higher levels of income *per capita*. In a situation of two possibilities, with identical terminal year incomes, the one with the lower rate of population growth in the period will have a higher level of income *per capita* and thus a higher rate of saving. Beyond this, the investment function is divided into two parts, one productive, the other termed "welfare". It is the latter part that depends upon the size and the rate of growth of population, but it is the productive investment that is the resultant residual from savings. This productive investment then determines the growth of the economy. From this very simple and illustrative model have come many variations by many authors, one even going so far as to state that there is a direct relation between the debt-service ratio of a country and the magnitude of its population control programmes.<sup>33</sup> Such was not the intention of Coale and Hoover, who merely wanted to draw attention to the intuitive relationship between the size and growth of the population and the rate of advancement of economic welfare.

30. This approach has been criticized in more recent years for a variety of reasons.<sup>34</sup> These reasons can be summarized by pointing out, first that personal saving comes from groups whose fertility is likely to be low already and whose consumption patterns are not likely to change with changing fertility; secondly, that among lower-income groups a lower dependency burden results in a higher consumption *per capita*, without affecting savings; and, thirdly, that the amount that Governments currently spend on population size dependent welfare investment is so relatively small that changing this type of activity over a wide margin has little or no over-all effect on over-all investment.

<sup>31</sup> See A. J. Coale and E. M. Hoover, *op. cit.*

<sup>32</sup> "Conventionally" should be regarded as referring to economics.

<sup>33</sup> Such a conclusion was drawn from an early descendant, TEMPO I.

<sup>34</sup> J. N. Sinha, *Macro-Models and Economic Implication of Population Growth* (Liège, Congrès International de la Population, 1973).

#### TEMPO MODEL

31. A direct descendant of the Coale-Hoover approach is the General Electric Company's TEMPO model formulated under the direction of S. Enke. The original version of the TEMPO model had the Coale-Hoover savings function, essentially:

$$S = aP + bY$$

where  $a < 0$ ,  $P$  = population,  $Y$  = income,

so that a higher population served to lower the savings of the economy and thus investment and growth. A later version added a link from population to the labour force and thus to production.<sup>35</sup> The current version, TEMPO II, is considerably more sophisticated.<sup>36</sup> The population section of the model consists of 65 cohorts, each with its own specific survival rate, an amount of detail which is, perhaps, unnecessary. Births are assumed to be a function of fertility, a variable which can be affected by expenditures on family planning (and in the aggregate by migration). Such expenditures, however, are an exogenous policy variable and thus are not a link from the economic to the population section. They do, however, come from available public sector resources and thus are a subtraction from resources that can be put into capital stock and thus into growth. Since the magnitude of such expenditure depends upon the size of the population (the policy variable being an acceptance rate), this constitutes a link from population to the rest of the model.

32. The economic sector of the model consists of a modified Cobb-Douglas production function that utilizes capital, educated and uneducated labour and assumes exogenous technical progress. There is a public sector that allows canalizing of resources into population-related activities and a foreign sector that allows foreign aid; but these are largely for the purpose of accounting and explanatory convenience. The labour force is derived from the population figures and the portions that are educated and uneducated depend upon expenditures for education. Here again, the expenditure is the product of the size of the population in the appropriate age groups and the policy target rates for enrolment in each of four levels of education. Thus educating the labour force, which increases its productivity in the production function, costs resources which could otherwise be invested in capacity. The key link from population to growth is, as before, the savings function, which, in this version, is expressed as a consumption function:

$$C = aYD + bP$$

where

$$b = d \left\{ \frac{YD}{P} \right\} \left( \frac{YD}{P} \right)_0^e \quad 0 \leq e \leq 1$$

<sup>35</sup> W. E. McFarland and others, *Description of the Economic-Demographic Model* (Santa Barbara, Calif., General Electric Company, 1968).

<sup>36</sup> W. E. McFarland and others, *op. cit.*

$YD$  is disposable income and  $P$  is population. This formulation clearly depends upon the value assigned to the parameter " $e$ ". If it is unity, then consumption is solely a function of income and there is no population link. If it is zero then one has the Coale-Hoover system, which is similar to TEMPO I. Such a formulation is designed to allow the model to meet the criticisms of various authors (generally by setting " $e$ " close to 1.0), and, at the same time, is in a form which would permit estimation on developing country data so as to ascertain whether " $e$ " was significantly different from unity. In terms of sensitivity analysis, it is clear that, in the model, growth of income *per capita* will be quite sensitive to changes in this parameter and that it is through this parameter that demographic changes are principally transmitted to the economic subsystem.

#### INTERNATIONAL BANK FOR RECONSTRUCTION AND DEVELOPMENT—MEXICO

33. A far less ambitious model is one that has been used in the International Bank for Reconstruction and Development (IBRD) for routine long-run projections, a typical example of which can be found in an analysis of the likely trends in Mexico to the year 2000.<sup>37</sup> In this analysis, the central projection is that of population, an analysis of which is carried out by five-year cohorts with country-specific mortality and fertility data. Fertility assumptions are then introduced in order to produce three projections: continuation of current trends, moderate effort on fertility reduction and optimistic assumptions on fertility reduction. In general, the moderate effort projection is used as a framework upon which to place the economic and resource projections. Thus, the linkages all go from population to resources and to the economy; there are no linkages back to the population projection, which remains fixed throughout the analysis. In the Mexican case, the key resource constraints were land, water and energy. For each of these constraints, a projection of potential supply was made, and for water, this was done on a regional basis. Each supply estimate was then compared with the likely demands for the particular resource over the range of population projections, and, in the Mexican case, it was found that only energy would be a constraint. This constraint, however, is assumed to be satisfiable from imports; thus the analysis turned to an exercise in exports and balance of payments projection. At the same time, rough targets for output were made so that the general framework and magnitude of the macro-economy could be seen. This, then, forms the foundation for an assessment of employment-potential utilizing known employment trends and elasticities on a sectoral basis, which can then be compared with the potential labour force in 2000 to arrive at an idea of the magnitude and gravity of the unemployment situation in that

<sup>37</sup> This model was built in connexion with the International Bank for Reconstruction and Development basic economic mission to Mexico in 1972.

year. Lastly, given the potential number of people and their location, an analysis is made of the potential deficit in social capital and the costs of filling it. This latter set of figures can be fed into a public-sector model, which itself is linked to the macro-model and can thus be used to estimate necessary fiscal policy. This model differs from most of those discussed in this paper in that it looks only at a target date and does not try to simulate the system (other than the time-dependent population and external debt sections). It is thus much less deterministic while, at the same time, being more closely focused on the qualitative and semi-quantitative aspects of economic and social policy.

#### BANGLADESH MODEL

34. A more deterministic system has been built by Dorfman of Harvard University as part of the East Pakistan<sup>38</sup> Land and Water Resources Study. This model begins with three exogenous population projections to the year 2000 (ranging from increases of 2.5-3.25 per cent per annum) and then seeks to determine what is necessary for the growth of gross domestic product (GDP), domestic savings and taxation, and foreign aid in order to achieve an employment rate of at least 95 per cent at target dates. As in most of the models discussed in the paper, there are no links from the economy to population; rather, population is determined *a priori* and is the framework upon which the rest of the analysis is based. Moreover, the model requires that an actual growth path be calculated from the present to the target date. The economy is divided into seven productive sectors, each of which is constrained to follow a sector share of total output derived from international cross-sections. Every five years, an iterative calculation is made, using sectoral productivity trends from cross-section analysis, to arrive at the level and composition of income that will meet the employment targets. This level of income then uses cross-section estimates of saving to determine the internal resource generation and similar estimates of ICOR to arrive at the demand for such resources. The deficit then becomes the total foreign capital inflow: private flows plus official aid necessary to achieve the target. This type of model, therefore, does not consider the impact of population on physical resources and assumes that there is no practical limitation on the supply of such resources. It is essentially an employment-population driven financial analysis.

#### UNITED STATES COMMISSION ON POPULATION GROWTH

35. A fairly well developed model was utilized by the United States Commission on Population Growth and the American Future. With respect to the period 1970-2020, this model is, perhaps, the most detailed and sophisticated of the national models. Like many

<sup>38</sup> Now known as Bangladesh.

others, however, its direction of causality is from two alternative exogenous population projections to a whole host of economic, physical and social considerations. Moreover, it concentrates on the United States of America; and although it acknowledges the rest of the world, it does not, in general, look beyond the national framework. Specifically, it ignores most of the global problems raised by the world models, even though the United States would be one of the chief contributors to the problems raised by those models. Beginning with two population projections, the analysis then posits two different economic growth paths. The high alternative assumes productivity to grow at 2.5 per cent per annum and work hours to decline by .025 per cent per annum (this generally expresses the current trend). The low-growth alternative has the same productivity but man-hours decline by 1 per cent per annum. The two population and the two economic projections give four alternatives with income *per capita* ranging from two to four times current levels.

36. The key vehicle for carrying out the projections is an adaptation of the Maryland Interindustry Model. This 185-sector model was modified in several ways in order to be able to use it for long-run analyses: technological coefficients were introduced to allow the coefficients of the matrix to reflect anticipated technological changes, certain linearly decreasing functions (appropriate for short-term but not long-term forecasts) were replaced by exponential delay-functions, and specific pollution and treatment cost coefficients were introduced. Moreover, the model was given a new set of consumption functions that related to demographic as well as economic characteristics, a public sector set of equations responding to similar variables, specific relationships for about 20 commodities believed to be crucial over the period and an explicit pollution section. This enlarged model thus allows a fairly detailed analysis of the economic, resource and environmental impacts of different population and output trends.

37. Such a framework represents perhaps the most useful and meaningful way of looking at developed countries. However, its data and operational requirements are inappropriate for developing areas as are certain parts of the analysis (typically those dealing with pollution and physical resource constraints). The beginnings of a valid world model might well be made by combining this model with similar analyses for Japan and the Common Market.<sup>39</sup> Such a formulation would, then, define the magnitude of the resource and pollution problem for the world as a whole and would give an indication of the demand on resources that the developed countries will be placing on the rest of the world. The developing countries require less sophisticated models and ones that concentrate more on the interactions flowing from economic factors and resources to demography. Only after well worked-out models of both types are available, and more importantly, after it

<sup>39</sup> This project is, in effect, what is now being carried out under Leontieff.

has been possible to model the interactions between rich and poor on the world, will it be possible to approach an operationally valid world model.

#### INTERNATIONAL LABOUR ORGANISATION: BACHUE MODEL

38. The model called Bachue,<sup>40</sup> that is being built by the International Labour Organisation (ILO), is based upon a systems analysis that seeks to focus on the links between population and economics in both directions, specifically concentrating on the economic determinants of demographic variables, which are not treated in the conventional models and are as yet limited in the world models. As this is an ongoing study in an ambitious long-term project, there are no "results" as yet;<sup>41</sup> in fact, the modellers have been careful not to draw premature conclusions either about the structure of underdevelopment or the future of mankind. The model has been extensively worked out both in the demographic section—with age, sex, location and education cohorts; and in the economic section, with inter-industry analysis covering seven sectors. The usual links from population to the economy are found in this model; much more important, however, are the specific links from economic to demographic variables. Births, deaths, migrations, labour force participation and demand for education are all related to variables outside the population section.

39. As it now exists, Bachue is a carefully delineated system potentially capable of performing a detailed analysis and projection of a developing country. The largest job is still before it, however. This task is to obtain data for a specific country and to verify that the specified interactions do indeed exist, and that, moreover, they are important and necessary parts of any forecasting system. Bachue is still far from being an operational tool that can provide specific information on long-run outlooks or that can provide specific answers to the questions raised by the world models. The key question, which Bachue has the framework to address even now, is how quickly the demographic variables, and particularly the level of fertility, react to economic and resource changes. The world-modellers imply that the reaction time is too long to prevent collapse; the optimists claim that it does not matter because technology will save the world. It may well be that demographic variables will act quickly enough to make most of the doom prophecies irrelevant. Bachue seems to be an appropriate framework for looking at this question.

#### LATIN AMERICAN WORLD MODEL

40. Two models are of interest more for their objectives than for their structural content. Both the Latin

<sup>40</sup> Bachue is the Colombian goddess of love, fertility and harmony between nature and man—a fitting title for an investigation into the long-run future for mankind. See Richard Blandy and René Wery, *op. cit.*

<sup>41</sup> Preliminary runs indicate that considerably more research is necessary.

American model<sup>42</sup> and the Japanese model<sup>43</sup> are attempts to answer the problems raised by the world models, not by improving the data or changing the structural equations (although this certainly is done), but primarily by changing the objectives of society placed in the model. Thus, instead of asking whether mankind can survive ever-increasing levels of material income in a finite world, the models ask whether there can be a future where particular regional life-styles are viable. The Latin American model begins from the premise that every person has the right to certain minimum levels of food, shelter and material goods. This condition is considered to be the foundation of the model, a foundation which can be reached through the removal of "socio-political constraints". Once this initial condition is satisfied, then growth is permitted on a regional basis in accordance with regional preferences, subject, however, to absolute constraints of the environment and resources; it is assumed that the initial conditions do not violate any environmental or resource constraints. The model uses five regions, two developed and three developing; and after assuming the two groups are independent, explores the possibilities of interaction with the purpose of furthering the goals of the poorer groups. The hope of the modellers is to demonstrate that the achievement of certain minimum goals for all mankind is materially and technically possible, and in doing so to demonstrate that the whole business of doomsday models and predictions is essentially an affair of the developed countries: they will cause it and they will suffer from it, a large part of the developing world already being in the state of misery with which doomsday popularizers frighten their wealthy readers.

#### JAPANESE WORLD MODEL

41. With the Japanese model the circle of world models is completed. This model (or series of models) is being developed by the Japanese members of the Club of Rome (the group that supported the research for the World 3 model). The theme of the studies thus far undertaken is not collapse, but rather a search for feasibility. The first model seeks to answer the same question as the Latin model—how the needs of the whole world can be satisfied in a material sense. For this purpose, the model uses nine regions and six output sectors and looks at the flows necessary between regions (both trade and aid) that would be necessary to satisfy these needs. A particular focus is the redistribution of industry to developing countries. From such redistribution, a world production scheme, compatible with re-

source and environmental constraints can be derived. Another type of model by the same group seeks to answer the question of the viability of Japan and its particular set of values in the context of the world model. This model begins with the 56-sector input-output model and calculates the long-term outlook for the economy in a manner somewhat similar to the United States model. Population does not play a very large part in the model; it appears to be conventionally defined and the linkages go only from population to demand.

#### CONCLUSIONS

42. This paper has presented the highlights of a number of models concerned with the interactions between population, resources and the environment. It has dealt at length with the world models because of the considerable interest they have generated. It has been argued that these models are generally underspecified and currently serve the purpose of calling attention to the global problems arising from population growth and possible limitations of natural resources. The discussion has also covered a series of national models in which the interactions are specified in varying degrees of detail, but which do not consider the global problem at all. Such models, most of which are still being actively worked upon, show promise of being able, eventually, to throw light on these interactions, particularly in the developing countries, where knowledge is very deficient. Most models have a series of interactions from population to economics; but even here, when one gets into the questions of employment and income distribution, the answers and the relationships are far from clear. Few models have the interactions that go in the opposite direction—from economics to population. Yet these are the keys to a viable alternative for the vast mass of impoverished humanity.

43. It is clear that excessive rates of growth of population are an impediment to economic and material progress; and yet the conventional wisdom seems to say that unless there is economic advancement, population growth rates will not fall. Historical evidence shows the birth rate falling continuously as *per capita* income grows—this curve is embedded in the World 3 model. In a completely specified world model, the key to global equilibrium would be the rate of decline of this curve; it is clear that the historical rate is much too slow to avoid widespread global misery. However, it is only through investigations, such as those which form an integral part of the Bachue system, that it will be possible to shed some light on this type of interaction and to discern which areas of it are amenable to policy.

## CRITICAL REVIEW OF POPULATION-RESOURCES-ENVIRONMENT MODELS \*

*Amilcar Herrera* \*\*

1. In his paper "Population, environment and natural resources: a critical review of recent models",<sup>1</sup> N. G. Carter reviews some of the models recently designed or being designed. His excellent critical review covers practically all major aspects of these models and concludes with the advice that, in the future, all efforts should be concentrated on the study of the population-economic system relationship.

2. As a complement to Carter's work, the present author would like to add a few comments on the conceptual aspects of the models, which seem important, mainly because their neglect in some cases contributes to bringing into disrepute a tool that is extremely valuable for the exploration of contemporary problems.

### THE EPISTEMOLOGICAL NATURE OF GENERALIZATIONS INCLUDED IN THE MODELS

3. One of the central problems of the interpretation of results obtained by means of a model refers to the logical-epistemological nature of the conclusions, as well as to the assumptions introduced into the model. The assumptions used, which are quantitatively expressed by means of variables, parameters and their interrelations, are of very different natures. Generally speaking, they belong essentially to three types.

4. First, these are those relationships which epistemologically can be assimilated into natural laws. As a rule, only few of the assumptions of a model belong to this class. In the model of the Massachusetts Institute of Technology (MIT), for instance, the relationships characteristic of this group are those which link pollution with life expectancy and the death rate, some of those dealing with the internal relationships of the population sector and, in part, those concerning non-renewable natural resources.

5. Generalizations or assumptions that partake of the nature of general laws are, obviously, deterministic. If their results are negative for society or the individual, *a posteriori*, corrective steps may be taken (for instance, curing the persons who have been affected by pollution) or attempts may be made to eliminate their causes (for

instance, avoiding the release of pollutants) but the causal structure which is at their source is unchangeable.

6. Secondly, there are socio-historical trends or generalizations. Some of the most important elements of a model belong to this epistemological class: patterns of population growth and geographical distribution of the population, urbanization rates and patterns, patterns of consumption etc.

7. The general characteristic of this category is that it contains long-term phenomena arising from cultural, economical, geographical, historical and similar factors, concerning complex interrelationships of which relatively little is known. They do not, of course, partake of the deterministic nature of natural laws, since their causal structure can vary in time and has done so historically. Thus, the determinative nature of geography, for instance, which was very important in the past due to the necessity of locating the population near the most essential resources, becomes less and less important as progress in the fields of transport and energy transmission and in the ability to alter the environment etc. makes the location of these resources irrelevant. Another example is the effect of an improved level of living on the growth rate of population. Recent history shows that, at first, a small improvement in the standard of living causes an increase in the rate of growth due to the sharp decrease in the death rate, particularly among infants. A greater and more sustained improvement, however, tends to result in a decrease in the rate of growth of the population. In these cases, however, historical variations tend to be rather slow.

8. Thirdly, there are those elements which sometimes have a decisive effect on the behaviour of a model, but which can be modified relatively rapidly by the decisions of Governments or of groups holding most of the political and economic power within a society. Examples are the rate of savings and investments, the structure and scope of education, the capital-labour relationship, the availability of housing etc. The main difference between this and the previous class is that, although these elements are also the results of historical trends, their causal structure is much simpler and better known, which makes them easier to modify.

9. The differentiation of these three categories of generalizations—which does not pretend, especially with regard to the last two, to be exact nor epistemologically exhaustive—is commonplace; but failure to make a clear

\* The original text of this paper (E/CONF.60/SYM.III/27) was submitted to the Symposium on Population, Resources and Environment, Stockholm, 26 September-5 October 1973.

\*\* Director, Latin American Model, Fundación Bariloche, Buenos Aires, Argentina.

<sup>1</sup> This paper appears in *Population Debate*, vol. II, part five.

distinction between the three categories is a fundamental source of errors, which beset the interpretation of the results of mathematical population-resource-environment models. In fact, as the best known models are deterministic by virtue of their mathematical structure, their results are generalized and implicitly given the validity of natural laws. As a consequence thereof, generalized conclusions, which are the result of a complex interaction of short- and medium-range historical trends, acquire, because of the mathematical methodology used, a mark of inevitability which is characteristic of natural laws. The model, thus, becomes an autonomous instrument, the validity of the results of which appears to be relatively independent of the epistemological nature of the assumptions used. This is the well-known case of the MIT model.

#### VALIDATION OF THE RESULTS

10. This leads to the crucial problem of the validation of the results obtained when using a model. When his models yield results that are incompatible with common sense, Forrester takes it to be a proof of the counter-intuitive nature of the social systems, which agrees with what has just been said about the special quality implicitly assigned to the generalizations introduced in the models. In fact, it is only in the case of natural laws, which are empirically deduced, that counter-intuitive results may be accepted without further discussion and, even then, only after an exhaustive analysis of the conditions under which the experiments were carried out. The most salient example of a "counter-intuitive" experimental result is perhaps the one obtained by Michelson and Morley in their investigations of the velocity of light, which was decisive in the elaboration of the theory of relativity.

11. In the case of social phenomena, the situation is obviously very different. The few generalizations that are sometimes called laws are of too general a nature to be of much practical use. Also in social phenomena, the number of variables is, in general, much greater than in natural phenomena, a great many variables are difficult to quantify, experimental verification is not possible etc. In many cases, there is an obvious tendency to validate the conclusions of a model by the mere fact that it is "stable" and that its results are coherent. This only proves that the hypotheses represented by the model do not contain any inconsistencies or breaches of logic. In other words, the hypotheses and their relationships are formally correct. On the other hand, it says nothing about the correspondence of each hypothesis with the factual world it pretends to describe.

12. In short, the only way of evaluating the reliability of a model is by having a group of experts analyse its results. It should be borne in mind that a mathematical model is the formal and concrete transposition of a mental model, which, in its turn, is based on experience. This experience is, in general, very extensive and it has been put to the test of numerous

crossed inductions based on many cases similar to those represented by the model. This does not mean that a conclusion must be rejected only because it contradicts the experts' experience. It means, rather, that an exhaustive analysis of the assumptions of the model must be made before the conclusion can be accepted.

13. In this respect, the MIT model is illustrative. Several among the most notable deficiencies of its premises have been correctly pointed out by Carter. However, it would be to the purpose to consider, also, some theoretical problems related to the treatment of non-renewable natural resources and to the function of production, because these are assumptions that, in different ways, have a decisive influence on the behaviour of the model.

14. The two basic assumptions of the MIT model concerning mineral resources are:

(a) The total quantity of mineral resources that is still available on earth is enough to cover the needs of mankind for 250 years at the current rate of consumption. This duration is deduced from the figures for world reserves published by specialized agencies, particularly by the Bureau of Mines of the United States of America. Considering that the duration of these reserves varies for the different mineral raw materials, 250 years is considered to be a reasonable average. It presupposes, furthermore, a complete interchangeability between the different minerals;

(b) As the stocks of non-renewable natural resources diminish, the cost involved in obtaining each additional unit increases, due to the fact that those reserves which are of a higher "quality" and of easier access have been located and exploited first and that more effort (capital) is needed to exploit those which are less accessible and of lower "quality". The cost is measured in terms of the fraction of the total capital of the world that must be assigned to the exploitation of mineral resources. The increase in cost is a function of the remaining fraction of the original stock of available mineral resources. As this remaining fraction approaches zero, the fraction of the capital needed to extract natural resources approaches one, i.e., the total available capital, with detriment to all other activities of society. By this simple mechanism, the progressive depletion of mineral resources promptly brings about the collapse of the system.

15. As can easily be seen, the entire structure and, therefore, the validity of this part of the model, depends upon its ability to establish the total quantity of mineral resources available to mankind.

16. The scarcity hypotheses of the MIT model have long been used in economics and were developed in their general outline by Malthus and Ricardo. Malthus, who dealt especially with the problem of food, presupposes the existence of a finite and known quantity of resources, in this case land. To begin with, it is assumed that production increases as the area of occupied land increases. During this phase, that is, while there exists

unused land, the production cost remains constant. But when all existing land has been occupied, a limit is reached beyond which the production of each additional unit can only be attained at a higher cost. A point is reached where an increase in the expenses no longer means a higher yield, and the limit of possible production would then be reached.

17. Ricardo's hypothesis, seemingly more applicable to non-renewable resources, does not necessarily imply a finite quantity of resources. It assumes that the economically more profitable resources will be used first and that less adequate ones will gradually be incorporated, as the former ones become depleted. As a result, the cost of production increases from the beginning of the exploitation until it reaches limits that make the exploitation socially unacceptable.

18. The MIT model combines both scarcity hypotheses. It incorporates Malthus' assumption that resources are limited and Ricardo's hypothesis of a diminishing return from the beginning of production. No wonder that this combination of the most negative elements of the two hypotheses results in a model that is easily explosive.

19. One may ask to what extent any of the two scarcity hypotheses can be applied to mineral resources. Taking into account the definition of "reserves"—the material that can be exploited under current economic and technological conditions—it is obvious that Malthus' assumption of a known fixed quantity cannot be applied. It would only have a theoretical meaning if it were assumed technology and economic conditions were constant. In this case, the total resources would be those which could be exploited under current conditions, and a sufficiently detailed exploration of all eventually accessible parts of the earth would make it possible to establish their volume exactly. Yet, it is meaningless to use the figures recorded in the inventories that are periodically published as representing the totality of the resources obtainable under current conditions on this planet. These figures only represent a fraction, possibly a very small one, of the total resources of this kind. Nevertheless, the basic difficulty in connexion with ascertaining the volume of the earth's total reserves is the fact that whether given material is being considered as a resource or not depends upon technological and economic conditions that vary with time. Since these conditions cannot be foreseen, except for the very near future, the total quantity of resources that are possibly available to mankind is intrinsically unknowable.

20. Ricardo's hypothesis, although it at first appears to be better adapted to mineral resources, is also impossible to apply. Even if constant technology and economic conditions are presupposed, the assumption that the economically most convenient resources are exploited in the first place would require a prior and complete knowledge of the location and characteristics of all the obtainable resources that exist in all accessible parts of the earth. This condition has never been fulfilled and the reserves that were exploited first were those

which were easiest to locate and those which were, at that time, nearest to the production centres, this having nothing to do with the economic "quality" of the deposits. For instance, the European iron-ore deposits with relatively low iron content began to be exploited before those of Lake Superior with their high-grade ores, simply because the industrial revolution began in Europe and reached the American continent later.

21. However, it is when technological change is introduced that it becomes apparent that Ricardo's principle cannot even be formulated in an intelligible manner. In fact, each technological advance modifies the criteria that have to be used in order to ascertain which resources are most advantageous from an economic point of view. A few decades ago, the most convenient manner for obtaining nitrogen compounds for fertilizers was to extract them from the deposits of natural nitrates. Now they are produced from the nitrogen in the atmospheric air. Is there any sense in asserting that there has been a transition from a resource that was more convenient, from an economic point of view, to another that was less convenient. The same thing can be said about the changes in the type of resources used to produce other raw materials of mineral origin, due to the technological advances that have taken place since the beginning of the industrial revolution.

22. The effects of the treatment of the production function in the Meadows model and in other models under construction are not obvious to a similar degree, but they are also potentially catastrophic. In these models, a production function (3:1) without substitution issued on the assumption that, historically, the scarce element has always been capital. This assumption does not take into account the fact that in developing countries the rate of capital formation is very slow with respect to the growth rate of the population. The result is that, if it is not assumed that the surplus labour force can generate capital, which is absolutely contrary to historical experience, the rate of employment grows very slowly, maintaining a high level of unemployment. This hypothesis has been verified in the Latin American model, which includes sectoral production functions with substitution elasticity. Runs were made in which the production function coefficients remained constant with respect to current values. As can be seen, the Meadows model has very sound reasons for showing "counter-intuitive" behaviour patterns.

#### THE POPULATION PROBLEM IN MODELS

23. In his work, Carter points out that in all the examined non-"Doomsday" models, population influences the economic system, but not inversely. In the Doomsday models, the cycle is complete, but very weakly designed. Thus, in a typical model, a projection of the population is used, covering, as a rule, a period of about 50 years. This procedure is justified on the assumption that, due to the nature of population dynamics, the risk of error is relatively small for such a period.

24. However, the necessity of designing models in which population is a variable, depending upon endogenous socio-economic variables, does not reside in the need to obtain quantitative results that are more exact than in projections, but in the need to know which factors influence population evolution. This is fundamental because many of these models are being used to recommend birth-control policies without giving any explanation of which factors really bear upon birth rates. As a result, they usually end by recommending investments in family planning or contraceptive measures, both of which have greatly differing effects at different times and in different cultural environments, and are, as a rule, inefficient.

25. The Latin American model is a good example of a new point of view. It includes a submodel with more than ten socio-economic variables which determine population: calories and proteins *per capita*; housing shortage; literacy; urban population; rural population; economically active population in the secondary sector; economically active population in the primary sector; etc. All these variables are endogenously generated by the model, making it possible to determine how the population evolves in relation to the changes in the basic socio-economic variables. The model has already been tested, using historical series, and the results were remarkably exact. The adjustments obtained in the population variables are: life expectancy at birth (0.94); birth rate (0.82); crude death rate (0.83).

26. It is also necessary to point out, even though it seems superfluous, that, in a world-wide model or in a model comprising large areas, especially in the developing countries, it is necessary to use for the population sector, as well as for the other sectors, indicators or variables the meaning of which is as clear as possible and on which adequate information is available. Some models contain such variables as crowding, investments in family planning and availability of medical assistance, which satisfy none of these conditions. Crowding varies immensely within each country and even if it is multiplied by an income indicator, it is very difficult to endow it with any genuine quantitative significance. Investments in family planning have been applied in few parts of the world and for too short periods of time to permit the drawing of valid conclusions. Furthermore, it is known that their results vary greatly with cultural conditions. As for the availability of medical assistance, in the tests made with the Latin American model, this indicator proved to be practically irrelevant in comparison with the aforementioned socio-economic indicators.

#### CONCEPT OF EQUILIBRIUM OF THE ECOSYSTEM

27. The idea of equilibrium in ecosystems is one of the most vaguely used concepts in a large part of the abundant literature on contemporary problems. When introduced into mathematical models, this concept does not increase its precision, even if quantified, but

becomes much more dangerous. It is quite usual now to forecast, as is done in the MIT model, the "collapse" of the ecosystem within a relatively short time.

28. In this respect, it should be borne in mind that:

(a) No ecosystem of any importance has ever—in the entire history of the earth—been in equilibrium; otherwise, the evolution of life would have been impossible. There are many possible states of equilibrium, and it would perhaps be more correct to speak of a series of states of equilibrium or of a "general direction of equilibrium" rather than of a single stable state;

(b) There are so many variables involved in a natural ecosystem, their quantification is so difficult and so little is known about their detailed behaviour that there is still no "complete" ecological system (in fact, the only ecological system that can properly be defined as such is the biosphere) whose representation by a mathematical model has been possible;

(c) For all these reasons, there is a tendency to underestimate the ability of the ecosystem to adapt itself to the influence of the disruptive factors introduced by mankind.

29. This does not imply a denial of the fact that many of the values of modern society are intrinsically destructive for the environment, but much more investigation is required before this effect can be quantified and introduced in mathematical models. These can be very useful in showing which patterns of development have the least disruptive effects on the human and natural environment and, at the same time, which tend to fulfil the most fundamental needs of society.

#### PROJECTION MODELS *versus* NORMATIVE MODELS

30. A great many of the population-resources-environment models—and especially the Doomsday models—are merely projections and are implicitly based on the assumption that mankind's current tendencies are practically unchangeable. Historically, and particularly during the past two or three centuries, the fate of mankind has never been fixed in an unequivocal manner. In the face of global problems, there have always been sufficient degrees of freedom to allow for different alternative solutions. The chosen solution depends always upon the chooser's position in a concrete social, economic and political situation.

31. When Malthus propounded his theory of scarcity—the scientific basis of which was neither better nor worse than that of current Doomsday standpoints—the "solution" he postulated was not the only possible one, as has been proved by subsequent historical events and by Marx's refutation, which came relatively shortly after Malthus. It is clear that Malthus' position was the one that suited the interests of the governing classes of England. Marx's refutation does not so much derive from a different appreciation of "reality"—it being hardly more than a theory with very loose empirical foundations—as from a different conception of the forces that determine the evolution of mankind.

32. The current situation is very similar. Even if it is assumed that the current course of mankind might produce the collapse or serious disturbances in the natural ecosystem, it does not mean that there is one single solution for the avoidance of such risks. Owing to the enormous complexity of social organization, in conjunction with the progress of science and technology, the degrees of freedom at the disposal of the "human system" are now much greater than in Malthus' time.

33. The catastrophe forecast by many models now in fashion (mathematical or others) is the everyday fate of a large part of mankind. Hunger, illiteracy, premature death, lack of adequate housing etc.—in other words, wretched living conditions—constitute the common fate of the majority of the inhabitants of the developing countries. It is not necessary to wait 80 or 100 years for this catastrophe to be perceived, or for the effects of the depletion of natural resources or of increased pollution to be felt in the large centres of the developed countries.

34. The obstacles to an adequate development of mankind are not so much material, at least not for the foreseeable future, as socio-political; and they depend upon the current distribution of power at the international level as well as within each country. This is revealed in the growing international gap, as it is in the gap within countries, particularly the developing countries.

35. If these tendencies should persist, mankind will suffer a real disaster long before any limitations in the ecosystem become perceptible. The growing pressure of the "marginal" masses will most probably cause the breakdown of the international system through a series of conflicts on a continental scale. The current situation of the world and the events of recent years leave little room for doubt on this subject.

36. The foregoing statement is not meant to deny the fact that, if mankind's behaviour continues along current trends, the degradation of the physical environment may become a very serious problem. It probably will not take the form of a complete depletion of non-renewable natural resources or of a lethal increase of pollution. However, the problem of uncontrolled urban agglomerations and of the general deterioration of the environment, generated by a culture the sole aim of which appears to be to increase the consumption of

material goods up to irrational limits, can give rise to living conditions that are almost as disastrous as Malthus' scarcity.

37. A simultaneous consideration of the two basic problems now confronting mankind—internal chaos and degradation of the physical environment—makes it possible to redefine the concept of the human ecosystem. It has generally been defined as the physical environment in which mankind is inserted. There is a tendency to handle the concept as if there were two relatively independent but interrelated systems. It is assumed that the internal relationships of the human "system" have little to do with the physical environment.

38. However, the truth is that the influence exerted by mankind on the physical environment basically depends upon the social organization it adopts and upon the system of values sustaining it. A large part of the values of contemporary society are intrinsically destructive for the ecosystem, just as they are destructive for man himself, through a continuously increasing alienation. Mankind and the physical environment in which it is inserted constitute, thus, a single system, which can only be described by using social and physical variables.

39. In the current state of affairs in the world, the developed countries, being the beneficiaries of the global system, seek solutions that do not affect the social organization and the system of values on which this privileged situation is based. Reverting to the concept of ecosystem that was mentioned before, it is tantamount to making fixed constants of all the social variables. The system becomes determined by the physical variables, which are also assumed to be essentially constant. Consequently, "fatalistic" solutions make their appearance, based on the fundamentally static nature of the ecosystem, which is why there is so much talk about the inevitable breakdown of the state of equilibrium of the ecosystem, no account being taken of the obvious fact that there are many possible states of equilibrium.

40. Mere projection models can, therefore, scarcely be of any assistance in the solution of contemporary problems. It is necessary to design normative models which, by exploring all possible degrees of freedom in the complex mankind-resources-environment relationship, seek solutions that are not simply "crystallizations" of the current situation, perpetuating the advantage of privileged minorities.

**Part Six**

**POPULATION AND THE FAMILY**

## CULTURAL DEVELOPMENT, POPULATION AND THE FAMILY \*

Steven Polgar \*\*

1. Families, however one may wish to define them, are one of the most important institutions in human society. In explanations concerned with population dynamics, family types and family processes are often considered to be a crucial intervening factor between larger social units and natality. In this paper, the greatest emphasis is placed on the way changing socio-economic forces affect both family units and changes in population phenomena related to the way families function.

2. The first section of this paper is primarily concerned with three functions that are often associated with families: the sharing of subsistence activities in a small group (from two to not much more than 20 persons); explicit or implicit rules concerning permissible and prohibited partners in sexual intercourse; and joint care for and socialization of children.

3. Certain common assumptions about families have only recently been brought into question. Particularly confusing, when one wishes to look at this institution in a cross-cultural perspective, is the ethnocentric assumption that a single boundary will contain certain kinds of kinship behaviour, that the people within this boundary will form a co-residential unit (i.e., live in close proximity to one another), and that they will also be "normally" the only ones to perform certain household functions, such as cooking, childbearing and sexual cohabitation. This problem is discussed below in more detail (see paras. 27-32).

4. Family forms, natality and mortality levels, child-rearing practices and the outside forces affecting the family changed in various ways during social evolution. To divide human history into a "traditional" past and a "modern" future is to distort reality in the grossest way. The second and longest section of this paper is devoted to describing the relationships between society and the family, and between the family and reproductive patterns during the major stages of human evolution.

5. The last section of the paper briefly reviews some of the social policies that affect families and reproductive behaviour, comments upon the position of women and alludes to the implications for the future of the commune as a family form.

\* The original text of this paper (E/CONF.60/SYM.II/3) was submitted to the Symposium on Population and the Family, Honolulu, 6-15 August 1973.

### THE FAMILY AS A HUMAN INSTITUTION

#### *Joint subsistence*

6. If any one symbol can be chosen to best represent the family, it is the hearth or the common cooking-pot. In the duo-local residence pattern, where the husband remains in the household of his maternal kin and the wife in the household of hers (found among the Ashanti of Ghana), the wife will cook for herself and her children at her house and also send some of the food to her husband. The invitation to join the group eating a common meal is, in many cultures, both the most frequent and the most important form of hospitality towards one who is not normally a member of that group. In gathering-hunting bands, where many activities, such as large-scale hunts, caring for children and death rituals, are carried out by the entire band, food is very often divided up and cooked by smaller units which—for this and other reasons—can be considered families. Conversely, when large groups routinely eat in dining halls, as in labour camps, colleges or prisons, an observer will immediately know that "family life" does not exist in such a setting.

7. In societies based on the production of food rather than gathering and hunting, the family is often one of the most significant work teams and property-holding units. When lineages are present, as is the case in many independent village agricultural societies, rights to land will be held by the entire lineage, but particular fields or gardens will be assigned to smaller family units, which will then work them co-operatively and have rights in the products thereof. In feudal societies, the peasant family is very clearly the basic unit of production. Of course, there may be institutions such as "work bees", where the raising of a building or the preparation of a large feast provides an occasion for joint work by persons from many different households. But most productive activities will be carried out by the same group of people who also share rights in land, owe common obligations to the overlord, occupy a single cluster of buildings (set apart from other similar clusters) and jointly use many other material objects as well. The decline in the importance of the family in industrial societies, by the same token, is often attributed to the fact that husbands and wives and other members of the family group no longer "gain their livelihood" by participating in the same unit of production.

### Cultural regulation of sexuality

8. Enduring sexual bonds between males and females are found among many vertebrates, not just humans. To trace the origins of the human family to sexual bonds, as some others have done, would thus be erroneous. But with the emergence of speech, elaborate sets of symbols and culturally transmitted social rules of behaviour, the patterns of mating described as monogamy, polygyny, polyandry, group marriage etc., are no longer species-specific or group-specific behaviour, but uniquely human cultural patterns.

9. Sexual behaviour is regulated by social rules in all human societies. These rules encompass rituals of transition to adult status, courtship patterns, mate selection, number and classification of marriage partners, degrees of tolerance and prohibition concerning extra-marital sexual behaviour and proper and improper times for coitus. Such rules, furthermore, have considerable influence on the pattern of reproduction.

10. Puberty quite frequently occurs after mate selection has already taken place. The degree of emphasis on the puberty transition, what sorts of sexual behaviours are permitted before it and whether it is performed as each girl achieves her physiological menarche or is done for entire age sets, can influence the timing of the first birth. Whether sexual intercourse is permitted during courtship, and between which partners, has similar consequences. Transition ceremonies for males may also be relevant, as in the instance of the Gikuyu, where only a kind of bundling is permitted during the courtship period, while the boys are waiting for their "graduation" into the young men's age set.<sup>1</sup>

11. Mate selection is an extremely important process, which includes incest rules and exogamy rules, as well as preference rules for certain types of kin. Among the many theories concerning the origins of incest, one is of particular interest in the context of this paper. This hypothesis is that parent-child incest originated due to the low statistical probability in early human evolution that parent and child would be simultaneously in the reproductive age, and that, based on the Arensberg principle that norms follow action, rules specifying that another type of mating is to be sought would follow upon the very high probability that other than parent-child matings would in fact occur.<sup>2</sup> Matings between siblings and cousins among non-human primate troops are, of course, quite possible. In gathering-hunting bands of humans, interband exchange of members became ecologically advantageous and, eventually, normatively prescribed. As band exogamy arose, sibling-sibling matings became infrequent.

12. After the development of agriculture, local group size increased and its membership became more stable. With the establishment of lineages holding property in common, systematic linkages between these descent

groups came to be solidified through preferential marriage systems, e.g., of cross-cousins. Prescriptive cross-cousin marriage, however, implying that all marriages are to be so contracted, is demographically most improbable, given the birth and death rates which prevail in these societies.<sup>3</sup>

13. With social stratification, class and caste endogamy appeared. Furthermore, as is discussed more fully below, States tend to take over the regulation of sexual conduct, which helps to weaken the power of lineages.<sup>4</sup> After industrialization, many endogamy and exogamy rules become less important (with the exception of incest, about which the State continues to be concerned), and romantic love and personal compatibility emerge as important factors in mate selection.

14. The more restrictions placed on eligible mates, the more likely it is that the search for a suitable partner could delay the contracting of a marriage. In some societies, as in India, it is customary to guard against this contingency by beginning the mate-selection process long before puberty, and sometimes even before the birth of a son or daughter to the prospective in-laws. Conversely, when mate-selection rules are very relaxed, as in industrial societies, age of marriage can fluctuate rapidly in response to temporary factors.

15. Certain types of marriage patterns have been the subject of considerable research and debate with respect to their demographic effects. With polygyny, the preponderance of the evidence now favours the conclusion that it tends to reduce natality, at least in Africa, where it makes adherence to rules concerning long periods of post-partum abstinence more feasible.<sup>5</sup> Polygyny can also affect the age at marriage and the age differential between mates. When the incidence of polygyny is high, it is likely that girls will be married at a young age and often to older men; by the same token, young men may remain celibate for a long time, carry on extramarital affairs with—and often marry—older women as the first wife, all of which might lower average natality. Frequency of divorce, length of time between marriages and probability of remarriage can all affect the proportion of the reproductive period during which a woman is not exposed to pregnancy. Matrilineal descent<sup>6</sup> and the West Indian visiting type of conjugal relationship<sup>7</sup> are examples of marriage systems conducive to more frequent dissolution of unions and

<sup>2</sup> M. K. Slater, "Ecological factors in the origin of incest", *American Anthropologist*, December 1959, pp. 1043-1059.

marked variations in the frequency of exposure to sexual intercourse.

16. The suitability of different types of contraceptives may also be affected by the prevalent type of marriage. For example, in the nineteenth-century Victorian pattern, where the wife is not supposed to experience any pleasure during the sex act and the husband obtains his pleasure in extramarital settings, the use of *coitus interruptus* between the married pair is not too troublesome. In the Mediterranean conjugal relationship, the condom, being strongly associated with premarital and extramarital affairs, is not a suitable method to be used between husband and wife.<sup>8</sup>

17. Coitus before marriage and outside of its bounds is important when it circumvents some of the natality-reducing effects of marital patterns which would otherwise delay the age of first childbirth and lengthen periods outside of a sanctioned conjugal union. Recent trends in the United States of America, for example, show that a very large proportion of first marriages, particularly among couples under the age of 20, occur when the bride is already pregnant. Many extramarital liaisons, on the other hand, have a greatly reduced likelihood of contributing to natality because abortion and contraception would tend to be frequently used. Prostitution is important when marriage age for men is late, with long absences of husbands in labour camps and with some of the other aspects of the early stages of urbanization.

18. Times when sexual intercourse is deemed proper or improper are commonly prescribed in many different cultures. Beliefs, based upon the observation of oestrus in animals, that fecundability is highest just before and/or after the menstrual period, which was the dominant idea even in medical circles until Knauss and Ogino discovered it to be otherwise, would influence couples to have intercourse at these times if they desired a pregnancy, or to avoid them if they were not intending to have another child. Before hunting or raiding expeditions, before and during religious observances and during the late stages of pregnancy, abstinence is commonly prescribed. Mention has already been made of the post-partum abstinence period, which was found to be significantly correlated with natality levels in Nag's ground-breaking cross-cultural study.<sup>9</sup>

19. In some societies, as a couple grows older intercourse becomes less and less frequent and may even cease well before the end of the wife's reproductive period. On the Indian subcontinent, it is also considered shameful for a woman to become pregnant when her daughter-in-law is in the house and is beginning to bear children herself. Sexual intercourse may be encouraged

in connexion with some phases of the agricultural cycle, during early pregnancy, at the time of certain religious festivals and during the immediate period after the wedding (e.g., the so-called "honeymoon" of Western societies).

20. In sum, it may be observed that while the regulation of sexual activity is certainly not the foundation upon which the human family originated, nor its most important aspect, its various forms are important both for the relationships of the family to larger units of society and to demographic outcomes.

#### *Socialization of children*

21. The human infant is born at a much earlier embryological stage of development than is the case for other mammals. Such a biological change presupposes an arrangement by which new-borns and infants will be given a very large amount of care. The immaturity of the new-born also permits a great deal more learning to take place in the context of social relationships than in other mammals.

22. In contrast to many birds and lower vertebrates, the involvement of the human male in "parentalism" is not biologically determined,<sup>10</sup> and thus the degree of involvement of the father (as well as of relatives other than parents) in the socialization of children is highly variable. In gathering-hunting bands, the older children are often left to play by themselves, under the general supervision of members of the grandparental generation and others who remain behind in the camp while adults go out to collect food. When the camp is moved, the women carry both the larger part of the group's material possessions and the infants, which has important implications for the optimal spacing between births.<sup>11</sup>

23. In agricultural groups, toddlers are often placed under the supervision of older children, while infants are carried on the woman's back or placed on cradleboards or similar devices near the place where the mother works. So-called "extended family" households permit a great deal of co-operation in child-tending between sisters, co-wives and other related female members. (But such co-operation among relatives or non-relatives is also common in gathering-hunting bands and poverty neighbourhoods in industrial cities.)

24. The age at which children assume responsibilities in the area of subsistence activities tends to be lower in peasant societies than among gatherer-hunters, which reflects the external pressures on the household unit through rent, labour demands and taxes. Corresponding to the degree to which gender division of labour is emphasized, children begin to associate with male or female relatives, respectively, learning to take on adult responsibilities.

25. Specialists for the education of the young first appear in feudal societies, where their pupils will be drawn only from the upper classes. The institution of the public school emerges for the first time in industrial and late-colonial societies. Schools characteristically stress enculturation into the national society (or, in colonial settings, into the culture of the metropolitan society) at the expense of ethnic subcultures. Thus, not only is the socialization of children removed from the family setting, but the State can design curricula based upon the ideas of power-holders concerning the best interests of the country.

26. Schools differ from other types of learning situations by their predominant emphasis on verbal and written means of teacher-pupil communication, as opposed to imitation and guiding the learner's motions by direct physical contact. An interesting exception, however, to the latter kind of learning in societies that do not have schools, is the instruction given during puberty ceremonies. Along with many other practical and ritual matters transmitted at this time, the initiates may also be told about contraceptive and abortion techniques.

#### *Problems in the definition of the "family"*

27. Since such a large part of the social science literature on the family originated recently in the United States and in Western Europe, it is not surprising that it should be tainted by severe ethnocentrism and chronocentrism (the bias of looking at all historical epochs from the point of view of one epoch, such as the present). Since the "family" in late nineteenth- and twentieth-century Western societies represented a co-residential unit, composed of people closely related by marriage and descent, and the largest part of the domestic functions of child-rearing, eating, money-sharing and the like were performed within this co-residential group, the three separate elements of co-residence, domestic functions and intimate kin behaviour were conceptually amalgamated as "normal" components of "family" behaviour. When patterns were described, both within Western society and outside of it, which did not combine these three separate areas of behaviour, they were considered deviant and/or curious. But from a cross-cultural and historical point of view, it may be preferable to analyse these three domains separately, rather than assuming that they "normally" belong together in the same institution.<sup>12, 13</sup> Biological factors certainly do make it preferable that a mother and the infant she is breast-feeding reside in close proximity. But even in this respect, suckling by several women or hiring a wet-nurse is possible. There is also no need, as is illustrated above, for the husband to

reside under the same roof as the wife, or for completely weaned children to remain with their mother. Sexual intercourse can—and does—take place in many other places besides the one where the wife sleeps.

28. The intimate relationship between the mother and her children does indeed condition this to be the closest kinship found in all societies; adoption, however, can lead to an equally close relationship, despite the absence of the biological bond. In many societies, the second closest bond is not between husband and wife, but between siblings, particularly those of the same gender. With matrilineal inheritance of property held by males, there is an inherent conflict between the married pair, to the extent that the husband's loyalties are split between his own children and those of his sister, and a wife might indeed frequently importune her husband to give presents to "her" children while he is alive and not let all his valuables remain for his matrilineal kin after his death. Mention has previously been made of the high frequency of divorce in matrilineal societies.

29. The dichotomy between "nuclear" and "extended" households is neither as simple nor as fundamental as most Western-trained social scientists would make it appear. In societies where the continued residence of the family head's children, with their spouses and own children, in the parental home is an expressed ideal, only a minority of households are found in fact to have such a structure.<sup>14</sup> Of course, a separate residential location for an elementary family of husband, wife and their children does not mean that other relatives may not be highly significant in helping to raise the children, giving and receiving money or gifts, or influencing decisions related to family planning.

30. Increasing numbers of people in industrialized and colonial societies spend considerable portions of their lives in such settings as dormitories, barracks or labour camps, which are not "familial" residential arrangements at all. There are precedents for this, of course, in the monasteries of Christianity and Buddhism, not to mention the camps for warriors-in-training in the Zulu kingdom or the Ottoman empire. Servants and lodgers residing in households—also a pattern predating industrial society—are yet another phenomenon complicating the nuclear-extended dichotomy.

31. The novelty of the school as an institution for the socialization of children has already been commented upon. Other institutions in industrial societies that perform domestic functions include restaurants, hotels, house-cleaning services, baby-sitters, hospitals, old-age homes and visiting nurses. Many domestic functions were performed in pre-industrial societies, too, in locations other than the primary residence of family members. Not only did children, for example, move around to the residence of different kin, but many relatives and neighbours were free (and often indeed responsible) to nurture, instruct and sanction children in a number of

<sup>14</sup> T. R. Burch, "The size and structure of families: a comparative analysis of census data", *American Sociological Review*, March 1967, pp. 347-363.

"outdoor" settings. Few societies go so far as the Nyakyusa in having young people move out to form separate age-villages;<sup>15</sup> but peer groups have been of immense importance in helping children acquire physical, social and ideational patterns relevant to their culture. Food preparation, for social and ritual occasions, very often takes place outside of the family cooking-pot, and sexual liaisons—as mentioned above—occur frequently outside of conjugal unions.

32. All of these complexities should serve to caution the investigator interested in making generalizations about population phenomena relevant to the entire human species. Co-residential units are indeed an important locus for conjugal relationships including coitus, for childbearing and for the socialization of children; but it is singularly dangerous to equate them with two or three family prototypes, each of which is supposed to have particular characteristics relevant to demographic phenomena.

#### THE FAMILY IN HUMAN EVOLUTION

33. Some allusions have already been made to differences between human families and social congregations of other vertebrates, and to varieties of family forms at different stages of human evolution. In this section, productive activities, socio-political patterns, family types and reproductive behaviour are reviewed in a systematic historical sequence.

34. The dichotomy between "traditional" and "modern" types of societies and families, so often employed by demographers, sociologists and other writers, must be emphatically rejected as inappropriate to a scientific endeavour hoping to encompass all of humanity. The term "traditional" invokes a "mixed bag" of social patterns, which would include eighteenth-century French peasant homesteads with Australian aborigine bands, and plantation shacks in Santo Domingo with the shogun's palace in Tokugawa, Japan. By the same token, "modernization" often denotes nothing more than the process by which third-world countries are supposed to be remade in the image of twentieth-century middle-class patterns in the United States of America. There may also be a further implication that this "modern" state of affairs is some kind of inevitable millennium, rather than a brief (say, 150 years) and largely aberrant incident in human history.

35. Reviewing the development of the human family in an evolutionary perspective has the further advantage of giving a proper place to the biological substratum of human society, which developed during the period of at least 2 million years while human subsistence was based on gathering and hunting. One must also be aware, however, that many conclusions about the evolutionary past are based on inferences from contemporary peoples and living non-human primates. Ecological considerations, and occasionally the evidence

of archaeological research, can be used to buttress these inferences. This warning is not constantly repeated as the historical reconstruction is sketched out below, but it should be kept in mind.

#### *Non-human primate troops*

36. Monkeys and apes, with the exception of lactating infants, obtain all the food-stuffs they consume on their own; in other words, there is no sharing of food. The social cohesion of troops is thus not predicated on food-getting; neither is it based upon sexuality, since one can find instances of troops made up entirely of young males or of females and young. Probably the single most important reason for banding together is defense against predators. The most common composition of troops is one or more adult males, and a number of adult females, juveniles, immatures and infants.

37. There is a great deal of variation in the ecological adaptation of different primates, but a fundamental difference obtains between tree-living and ground-dwelling species. Sexual dimorphism and the size of the home range tend to be much greater among terrestrial groups. Field-studies of baboons, mountain gorillas and chimpanzees conducted in the past 15 years have been particularly instructive.<sup>16</sup> Most of their diet consists of fruits and vegetables, and the troop exploits a relatively restricted domain, usually called the home territory. Agonistic displays, both within and between troops, can occasionally be observed, but dominance behaviour (including hierarchies) serves to keep the situation generally peaceful. Individuals will occasionally shift from one troop to another among the baboons and gorillas; among chimpanzees the situation is considerably more fluid.

38. In most species of large primates, contrary to previous evidence, which had been based on studies in zoos only, there is a definite period of heightened sexual activity and a birth season.<sup>17</sup> During the period of lactation, the mother does not engage in coitus. Population density in situations where there has been no human disturbance of the environment is well below the carrying capacity. Immature primates engage in a great deal of play behaviour in peer groups, improving their motor skills in the process. Infants are at first tended only by their own mothers, with gradual participation of other females and occasionally males. Then, there is a very gradual process of social separation coincident with weaning. Except for gibbons, where for a part of the annual cycle a male and a female and some young will remain in steady association, social units resembling the human family are generally absent.

#### *Gathering-hunting bands*

39. In contrast to almost all non-human primates,

<sup>16</sup> See I. DeVore, ed., *Primate Behavior: Field Studies of Monkeys and Apes* (New York, Holt, Rinehart and Winston, 1965).

<sup>17</sup> J. B. Lancaster and R. B. Lee, "The annual reproductive cycle in monkeys and apes", in I. DeVore, *op. cit.*, pp. 486-513.

who will make their daily rounds together and often shift each day among several preferred sleeping locations, gathering-hunting bands establish a single home base which they occupy for weeks or even months at a time. From this home base, different subunits of the band will usually disperse to pursue varied food-getting activities; often, males will range further away in pursuit of game, while females and some youngsters collect vegetable products at lesser distances from the camp. Some individuals, including the old and many of the children, will remain in or near the camp a great deal of the time. Adults also may remain behind, for example, to work on tools, to rest or to engage in curing activities.

40. The transition from the twigs and stones occasionally used as implements by some monkeys and apes, to the tool-making and tool-using among humans is often considered the most important behavioural step in hominization. Bipedal locomotion, which may well have been encouraged by tool-using, is the anatomical criterion used to classify fossils as human. Consumption of meat is also a very important human characteristic (reflected in dental structures), although non-human primates occasionally eat insects or immature birds and mammals. Vegetable products still make up the largest part of the calories in the diet of all but the most exceptional gathering-hunting bands.<sup>18</sup>

41. Human reproductive physiology differs from that of most other mammals in three significant ways. First, among humans there is neither the annual (nor semi-annual) period of heightened sexual activity; nor—as a consequence—a definite birth season. Births are not evenly distributed throughout the year, but seasonal fluctuations in contemporary societies are relatively small and differ considerably from one place to another. Secondly, both sexual intercourse and impregnation can occur while a human female is lactating—a change which may have taken place at about the same time as the acquisition of a fully bipedal gait.<sup>19</sup> Thirdly, with an increase in the entire life-span, not only the gestation period, but the length of the human reproductive period, became longer. Taken together, these changes produced a situation where birth intervals in *homo sapiens* could become as short as 10 or 11 months, and the number of children born per average woman in a group could reach approximately 12, which is the Hutterite maximum.

42. However, except for those periods during which human population expanded over every continent except Antarctica, population increase during the Pleistocene seems to have been negligible. Given the possibility of doubling population size in every generation, even before the advent of modern public health and medical techniques, and given the universality of deliberate

natal regulation in all cultures described, the inference that infanticide, abortion induction and contraception were invented quite early in human evolution appears to be reasonable.<sup>20</sup> The most likely efficient cause for these natal regulation practices among gathering-hunting people is the difficulty of transporting more than one child unable to walk when the band is moving from one camp site to another.<sup>21</sup> The effect of these practices has been that population densities among contemporary gathering-hunting societies are considerably below the carrying capacity of the environment.<sup>22</sup>

43. In gathering-hunting bands, the camp site is divided up into dwelling-places occupied by such family units as a conjugal pair with small children, an older couple whose children are grown, an older person with an adolescent or an older person alone. These subunits will have cooking-fires of their own, but both uncooked food-stuffs and prepared comestibles are passed back and forth in elaborate systems of reciprocal exchange. The composition of a particular camp is in a constant state of flux, with people shifting their residence quite frequently. In some groups, there are seasonal shifts between larger and smaller aggregations; and at the point when the smaller groups reassemble into the larger ones, there can be a considerable change in the overall composition of the bands.<sup>23</sup> Work teams are rarely made up of the persons who eat food cooked on the same fire; rather—unless the entire band takes part in an organized activity such as a collective hunt—they will be composed of persons (usually of the same gender) who want to engage in a particular activity and find one another's company congenial.

44. Taking care of youngsters, to the small extent that they are not taking care of one another, is apparently the responsibility of any adults who may be in the vicinity at the time, as mentioned above. The assumption of adult responsibilities does not take place until well into adolescence. Marriage tends to be exogamous in the sense that close relatives and members of the same or adjacent band are discouraged from marrying one another.<sup>24</sup> Lineages for reckoning descent in mate selection occur and are very highly elaborated among Australian aborigines. These lineages, however, are not the basis for organizing work teams, and they do not have exclusive use-rights in productive resources. Rather, their primary purpose seems to be to link distant groups together to facilitate the sharing of resources; in Australia, there is a strong correlation between the harshness of the environment and greater elaboration of the marriage selection system, forcing

people to search for mates further away in proportion to the undependability of local rainfall.<sup>25</sup>

### *Independent villages*

45. The most significant turning-point in human history occurred when subsistence came to be based on the production of food from domesticated plants and animals. The transition to food production was a gradual process, preceded by an increased tendency to exploit smaller niches in an intensive fashion. The linkage of several of these niches seems to have been of particular importance; seasonal shifts in exploiting adjacent environments, transporting seed from one type of terrain to another and trade relations were particularly important in this process. There were at least three widely separated foci where this transition took place, each involving a different set of domesticates.

46. Various methods of reconstructing population change coincident with the transition to food production indicate that human numbers may have grown by as much as a hundredfold in a period of a few thousand years.<sup>26</sup> Considerable segments of the ecosystem were altered to produce materials for human consumption. Thus, it may be appropriate to refer to the "supportive" capacity (instead of the "carrying" capacity) of the environment: once human inputs changed the soil, the species of plants and animals, trophic relationships and transported materials from one location to another. Given the vastly increased supportive capacity then, the range of densities of human populations that have been observed during the independent village phase still remain very much below the maximum.<sup>27</sup> With this greater degree of sedentariness it was also no longer such a problem to have more than one infant per mother alive at the same time.<sup>28</sup> Children are given tasks contributing to production, such as keeping birds and other animals away from newly planted fields, weeding, tending flocks and taking care of younger children when the mother is busy.

47. Once the economy of a region was transformed to food production, population-stabilizing tendencies presumably became more pronounced. One of these tendencies was the maintenance of socio-political distance between villages. Intergroup raiding, while not unknown, was relatively rare among gatherer-hunters. In agricultural villages, particularly at the centre of groups expanding into an unused area and at the periphery of groups advancing against other peoples, raiding is quite common.<sup>29</sup> Characteristic of hostilities

at this stage of evolution is a pattern of shifting alliances between different villages, based upon proximity or kinship. This leads to a situation where the village which has defeated several others, and perhaps chased their inhabitants away, will eventually acquire enough enemies who will join together to restore the balance of power. Villages, as well as lineages, which become too large for the effective organization of agricultural pursuits (and/or the organization of cohesive social relations under the leadership of two or three temporary task-leaders) will split up into smaller units.

48. Natality-regulating methods already common among gathering-hunting people, such as infanticide, abortion and contraception, will be found among many agricultural people as well. The cross-cultural distribution of the long period of post-partum abstinence<sup>30</sup> indicates that this practice may well have emerged after the transition to food production.

49. With a greater degree of sedentariness and the presence of several kinds of domestic animals in close contact with the human population, the epidemiological factors influencing mortality changed considerably.<sup>31</sup> The cumulation of human wastes and the presence of alternative domesticated hosts for pathogenic organisms facilitated the adaptation of a number of disease organisms to humans, for example, the shigella and salmonella groups of bacteria. Cutting down the forests also facilitated the spread of infections for which insects act as intermediary hosts, such as malaria, relapsing fever and sleeping-sickness. Some of the diseases found among contemporary village agriculturalists, of course, were brought to them with the expansion of state and colonial societies; it is plausible to assume, however, that many of the human diseases that have the ecological characteristics described did develop in the village-agriculture phase of evolution. Endemic mortality, furthermore, was probably of greater importance than raiding in reducing the maximum rate of population growth, because endemic diseases would take their toll of children of both genders before they reached reproductive age, whereas raiding mostly raised the mortality of adult males and therefore did not necessarily have too great an impact on the total number of children born to each woman.

50. Archaeological evidence supports the hypothesis that villages in the earliest stages of the transition to agriculture often consisted of members of a single lineage.<sup>32</sup> Later, multilineage villages came into ex-

istence, and eventually the settlement pattern showed the emergence of social stratification. As stated above, lineages or lineage segments in agricultural villages usually control land in common. Animals, fruit-trees and agricultural implements, on the other hand, tend to be individually owned. The significant units in the reciprocal exchange networks often are villages or lineages, although individuals may be the actual trading partners. Important exchange relationships also obtain between cultivators and herders, despite the frequent hostility between the two groups.

51. The emergence of corporate groups holding rights to productive resources in common is likely to have occurred during the period of rapid population growth associated with the transition to food production. An "immortal" corporation based on descent lines makes much more sense when almost all lineages had a high probability of actually surviving through time; under conditions of population stability, the operation of random factors would cause a substantial proportion of "lineages" to die out. It is quite possible, therefore, that the original causative sequence between an increased number of children and unilineal forms of social organization was from the first to the second, rather than the reverse, as is commonly postulated by demographers.

52. In accord with the importance of descent lines, the socialization of children becomes the responsibility of adults who are kin rather than just whoever is in the vicinity. Furthermore, distinctions between different categories of relatives become important. Lineage exogamy, for one thing, will create a situation where one set of spouses (either all the husbands or all the wives) will have come from somewhere else to live in the village. Seen from the child's point of view, there will then be important differences in the people around him, according to which ones he will be likely to inherit from, with whom he will be most closely associated in work teams and whose relatives he will be allowed to marry. Thus, it is not surprising to find kinship terminologies and prescriptions for kinship behaviour which systematically distinguish relatives on the father's side from relatives on the mother's side and sometimes distinguish between relatives reckoned through each of the four grandparents. Children will be taught which categories of kin have to be treated in particularly respectful ways, which ones have a right to tell them what to do, which are expected to tease them and be teased in return, and which can be looked to for specific favours. Specialization of villages or lineages will also mean that different children might be learning different skills, such as those connected with pottery-making, weaving or collecting medicinal plants.

53. Finding potential spouses of the "correct" kinship relationship, as mentioned above, may present some difficulties, particularly as population growth slows down and random factors lead to increases in some lineages as compared with others, or to temporarily unbalanced gender ratios. Methods for "patching

up" the system of kinship affiliation have come into use in these circumstances, including adoption, fictive kin and simply redefining relationships to suit the necessity of the occasion.<sup>33</sup>

### *Feudal states*

54. Various circumstances may lead to the increase of power of one lineage over other lineages in an interdependent system.<sup>34</sup> Such circumstances include the monopolization of particularly important ritual functions, such as rain-making, the attachment of homeless client groups to a particular lineage and a strategic position in an exchange network. With social stratification, the dominant lineage may very well increase in numbers without splitting into new lineages. Larger population and the acquisition of greater resources and privileges cause an imbalance in the exchange system, which heretofore had been more or less symmetrical. Thus, the economic system gradually shifts from reciprocity to redistribution.<sup>35</sup> Goods and services are moved from the less powerful segments of the society to the more powerful, who, in turn, redistribute them in such a way as to consolidate and increase their dominance. While further specialization and technological development in stratified societies usually lead to increases in productivity, the transition from village agriculture to feudalism does not involve as great a change in the ecological system as the transition from gathering-hunting to food production. In short, what is different is the political economy, not the method of subsistence.

55. Centralization of this kind tends to be contagious, because the mobilization of resources and manpower possible for a stratified group will endanger neighbouring groups, unless they also can centralize in defense. Hostile relationships change from raiding to what may now properly be called warfare, and at this point, States can be formed by conquest. From social stratification, the sequence goes to chieftaincy, and from there to the complex political relationships of feudalism proper.

56. To a considerable extent, the authority of chiefs, kings or temples will conflict with the cohesion of lineages. One of the ways in which the central authority gains ascendancy in this contest is by interfering with some of the crucial functions of lineages, such as the regulation of sexual behaviour and marriage: incest becomes a crime against the deity or the laws of the State, for which punishment is now meted out by the king or his representative rather than the lineage elders; marriages must be sanctified or registered by higher

<sup>35</sup> K. Polanyi, *The Great Transformation: The Political and Economic Origins of Our Time* (Boston, Beacon Press, 1957), pp. 47-53.

authorities; adultery is an offence against "public" law and morality rather than an infringement of the rights of the spouse; and so forth.<sup>36</sup> Other mechanisms for centralizing power include requiring entire age-grades to do military service under the king, contracting patron-client relations between the paramount and individuals rather than kinship groups, enlarging the royal court with slaves and retainers, and endowing the person of the king with ritual meaning. Relationships between the king and his subjects, furthermore, may be phrased in parent-child terms, emphasizing both the benevolence of the paramount and the dependent status of the people.

57. In many instances, the residence of the ruler attracts so many people that a town develops around it. Artisans, traders, beggars, soldiers and others no longer engaged in food production make their home in the vicinity of the palace.

58. In the economic system of feudal States, the agricultural population has to produce a surplus which is handed over to the higher authorities. The rulers, as previously mentioned, redistribute some of these goods to their retainers. Quite often, the land itself will be expropriated from the lineages; either the lord himself or some underlings such as headmen will then control land use. Rights in the means of production will no longer be by virtue of membership in a lineage corporation, but through particular relationships with the ruler, such as kinship, clientage, shareholding or servitude.

59. These economic relationships have a major impact on population dynamics. As agricultural villagers are transformed into peasants, they must alter their subsistence activities so as to bring forth the surplus demanded of them. One way to do this is to increase the domestic labour force without a corresponding increase in domestic consumption, specifically by having more children whose labour will be under the control of the household head and who will eat less than they produce. Economic forces, therefore, most probably underlie the various social and normative patterns so often associated with high natality among peasants (e.g., early marriage, discouragement of divorce, quick remarriage of widows and widowers, heavy emphasis on the childbearing capacity of women and religious exhortation favouring high natality). The latter patterns are intermediary factors rather than an adequate explanation in and of themselves for population growth.

60. The feudal situation conditioned a major change in mortality patterns as well. The concentration of large numbers of people into towns and cities gave rise to a new epidemiological situation, one in which infectious diseases could develop for which humans were the only reservoir.<sup>37</sup> Typical of such infections are smallpox, typhoid fever and measles. In addition, the urban setting was very suited for the multiplication of rats, which in turn became a reservoir for plague. Together with urbanism, the intensification of warfare and the

reduced level of living of the agricultural population thus made the feudal period the worst in human history with respect to major epidemics.<sup>38</sup>

61. Stratification in the larger society tended to be reflected in greater inequality within the family as well. Under feudalism, women were usually relegated to a much more subservient position compared with their position in village agricultural societies.<sup>39</sup> In peasant households, they were not only expected to produce many children and to take care of domestic chores, but to participate in many of the agricultural activities. In most instances, however, they had very little economic independence and power. Family structure, furthermore, diverged considerably between the upper and lower strata of society. While the extended family may be aspired to by both segments of society, it was much more possible of realization for the *élite*.<sup>40</sup> Although the situation varied according to patterns of land-holding and technology, the resources of the average peasant homestead were insufficient to support more than three or four working adults (and this would include youngsters from the age of about 12), as well as dependents. Persons in excess of this number might have had to ask the lord for an unused portion of land, to become servants or to try to take up some occupation elsewhere. Dividing up the land—a short-term solution with usually adverse long-term consequences—was possible only if the peasant were a freeholder, a condition which did not generally obtain until the next stage of evolution, that of the market economy.

#### *Colonialism, the market economy and industrialization*

62. The subjugation of one State by another was, of course, an important feature of the feudal period. Some empires, such as those of the Romans, the Incas, the Mongols and the Imams of Oman, stretched over great distances and even across some bodies of water. But in the past 350 years, the use of guns and artillery ushered in a new kind of imperial relationship, namely, colonialism. Since these new empires were formed by the expansion of European countries (Japan joined them only at the very end of the nineteenth century) into the Americas, Africa and Asia, colonialism bears the imprint of European development.

63. It should be remembered that the primary impetus for these conquests was trade. Christianity and political control followed soon after the explorers and merchants, but were secondary in importance. Contagious diseases of European origin, however, accompanied the very first adventurers and even spread ahead of the conquerors themselves. The demographic impact of this factor was profound: the series of

<sup>36</sup> Y. A. Cohen, *loc. cit.*

<sup>37</sup> S. Polgar, "Evolution and the ills of mankind", *loc. cit.*

epidemics that swept over the Americas decimated the original inhabitants to perhaps as few as one twentieth of their original number.<sup>41</sup> In Africa, where many European diseases had penetrated long before Vasco da Gama, it was mostly the slave trade and the advent of guns which led to a serious decline in population. In the Pacific, diseases of European origin resulted in consequences as drastic as or worse than those in the Americas. In Europe, meanwhile, population increased very substantially, owing, at least in part, to the spread of the potato—a plant imported from the New World.<sup>42</sup>

64. Another fundamental change in Europe was the growth of mercantilism. Local and regional trade were institutions compatible with and well-integrated into feudalism; long-distance trade, however, was severely hampered by the existence of many boundaries and hostile relationships between principalities. The economic mainstay of the feudal aristocracy was land. The long-distance merchants and their allies at various courts had an alternative source of income: luxury goods from the "East". Mercantilism was the first step towards the development of a full-fledged market system.<sup>43</sup> It fostered the accumulation of capital and its investment in goods other than that produced by the peasants and local artisans. The basic principle of exchange was altered from redistribution to the buying and selling of goods at a price. In this process, money itself became a "good" rather than just a convenient medium of exchange, but the full commercialization of the two other major components of the market economy, land and labour, did not occur until the nineteenth century.

65. The acquisition of land in the colonies was easily accomplished; in some cases, the original inhabitants were simply exterminated by disease and by attempts to enslave them, as in the Carribean; elsewhere, the conquerors simply replaced the original feudal rulers, as in Central America; the lands were declared unused when the original inhabitants withdrew after severe epidemics, as in the Highlands of Kenya; or the native rulers were transformed into plantation superintendents, as in parts of Indonesia.

66. Capital and labour were, at first, more difficult to obtain. Several of the large colonial trading companies periodically went bankrupt, and Governments eventually stepped in to assume full political and financial control of the operations. In Asia and Africa, the labour problem was attacked mostly by taxation and forced labour, and occasionally by the transportation of indentured labourers. In many parts of the Americas, slavery became the dominant pattern. For a considerable time, however, the mortality of people removed from their villages to work in plantations and mines required constant replacements. Gradually, subtler forms of economic bondage were substituted. Indigenous forms

of family life and even of political relationships were allowed to continue during this second phase of colonialism, and the slave trade gradually came to an end. Colonies with substantial numbers of European inhabitants fought for—and eventually obtained—political independence, but remained closely tied to Europe economically.

67. During this phase, the population of the colonies began to increase at a rapid rate; in Java, for example, at an average of 2 per cent per annum during most of the nineteenth century.<sup>44</sup> Long before the introduction of mass immunization campaigns and environmental sanitation, the imposition of European rule, with the prohibition of internecine warfare, the improvement of transportation facilities and the unflagging demand for labour to produce goods for export were instrumental in bringing about this population spurt. From the peasants' point of view, the advantages of having a large domestic labour force, which had already existed under feudalism, were maintained and even strengthened under the colonial economic régime. Paying his hut tax, performing his labour duties in the fields of the *hacienda* owner or of the Government itself, or producing the share of the crop he owed to the overlord (whose status had been reinforced by the colonial administration) were made somewhat easier if he had plenty of hands available whom he did not have to pay.

68. In Europe at the time of Malthus, relations between landlords and peasants were changing rapidly. After the increase in population during the eighteenth century, aggravated by the enclosure movement and the importation of food crops from the colonies, rural unemployment and poverty worsened. The Poor Law Act of 1834, which reinstated the punitive work-house system, turned out to be a crucial step in creating a reserve labour pool which was essential for the development of industrial capitalism. Those who remained on the land were also brought into the market system as land rents became fully commercialized.<sup>45</sup>

69. With industrialization and urbanization, the middle class emerged as a significant force in the metropolitan countries. Clerks, small *entrepreneurs* such as money-lenders, teachers and similar occupational groups also developed in the colonies, but their proportion in the total population remains small to this day. Nevertheless, the market system began to penetrate the economy in the colonies too. The upwardly mobile middle class in Europe, seeing the advantages of transmitting as much capital as possible to each of their dependants, began to reduce their family size towards the latter part of the nineteenth century.<sup>46</sup> For the poor

in Europe and the rural masses in the colonies, additional children continued to provide the possibility of additional income. Those who owned freehold land, however, often had to divide it among more numerous heirs.

70. With the massive movements of Europeans to the cities and to the colonies, the elementary family unit of husband, wife and children came to be less closely tied to the network of kin and community in which it had been embedded under the feudal system. Child labour, and later the school, brought young people from the masses into direct contact with the institutions of the larger society. As current or prospective participants in the wage economy, the State, in its turn, came to have an interest in their intellectual, attitudinal and physical development. New institutions of mutual assistance among neighbours and kin in urban areas also developed which transcended the co-residential unit.<sup>47</sup> Sexual behaviour, mate selection, child-bearing and child-rearing nevertheless became a much more individualized affair, somewhat removed from the sanctions exercised by relatives, but also increasingly regulated by the laws of the state.

71. The third stage of colonialism, beginning in 1945, was marked by the emancipation of many third-world countries from the administrative control of the metropolitan States. As in the case of the countries which gained independence a century and a half earlier, administrative independence is not synonymous with economic independence. The requirements of the metropolitan States, however, have changed, and continuing population growth in the third world is no longer to their advantage. There is more than enough labour available to bring primary products to the point of export, and the increasing number of poor people is not providing the industrialized countries with a sufficiently growing market for their manufactured products. In those third-world countries, however, where significant steps have been taken towards equalizing the distribution of resources, the people themselves are once again realizing that having fewer children may be advantageous. Furthermore, patterns of greater independence from the supervision of kin are being popularized by the mass media. And, last but not least, the movement for women's equality is beginning to gain some ground.

#### CULTURAL DEVELOPMENT AND FAMILY DYNAMICS

72. The cultural developments of the past 350 years can be seen, on the one hand, as the culmination of nearly 10,000 years of increasing centralization of power, during which time the interests of families have been increasingly subordinated to the demands of state

<sup>47</sup> M. B. Sussman and L. Burchinal, "Kin family network: unheralded structure in current conceptualizations of family functioning", *Marriage and Family Living*, April 1962, pp. 231-240; M. Lüschen, "Family interaction with kin, and the function of ritual", *Journal of Comparative Family Studies*, Spring 1972, pp. 84-98.

systems; and, on the other hand, as the beginning of a new era in which all families and individuals are beginning to obtain freedoms and comforts unprecedented in human history. The centralization of coercive power has allowed for mass genocide, absolute dictatorship and pervasive propaganda campaigns of deception; the emergence of participatory democracy, however, promises to bring a new dignity and meaningfulness to human life throughout the world. Families are, at one and the same time, exposed to the vagaries of economic boom-and-bust cycles, the tyranny of police forces and the dulling idiocy of mass entertainment, as well as provided with some opportunities to develop their own styles of life, make use of highly effective health and family planning measures and spend large amounts of time together in enjoyable pursuits.

#### *Social welfare policies*

73. In gathering-hunting societies, the welfare of each individual is the concern of the entire band. In independent villages, each lineage looks out for its own membership. Under feudalism, the main thing the lord was supposed to do for his subjects, in exchange for their servitude and a large part of their production, was to help protect them from other lords, bandits and spiritual dangers. With the inception of the market economy, the State assumed control over most of these welfare functions; but, for the most part, it has exercised this power for the benefit of the *élite*. There is often a time lag between the destruction of the community mechanisms to take care of orphans, invalids and old people, and the assumption by state bureaucracies of somewhat equivalent functions. Poor-houses, prisons, mental institutions and the like serve not only as a means of keeping unwanted people out of sight, but as an object-lesson to the rest of the population that they should do their utmost to participate in the economy.

74. The high mortality and morbidity of children put to work during the early stages of industrialization certainly were factors in the passage of child labour laws; but the availability of other sources of cheap labour by the beginning of the twentieth century obviously made the passage of these laws easier. Improvements in the working conditions in factories and mines were obtained only after the bloody struggles of the trade-union movement, and conditions in agricultural labour in a number of countries still remain dismal. Support for able-bodied adults during periods of unemployment is a very recent development. In the face of continuing rapid urbanization, which aggravates the severe housing problem in most countries in the world, many countries are trying hard to speed construction, and in a few, such as China, policies discouraging migration to cities are also being attempted.

75. One programme of particular interest is the payment of family or child allowances. The main purpose of these allowances is to increase the health and welfare of mothers and children. But in a number of

instances such programmes had the goal of stimulating the birth rate. Studies have shown that no such effects could be demonstrated for Western Europe and Canada.<sup>48</sup> However, a slightly different policy was followed in Hungary. This policy allows working mothers to extend their maternity leave until the child is 3 years old and to receive a child-care allowance amounting to about one half of the average pay of manual workers. Among certain groups of families, a slight, short-run increase in natality was observed.<sup>49</sup>

#### *Health services*

76. Healers are probably one of the earliest specialists in human societies. In most cultures outside the Western tradition, healers will usually be as concerned with re-establishing the balance between a person's relationships with the social and spiritual environment as with the functioning of his or her body. During feudalism, medical practitioners concerned themselves mainly with caring for the *élite*. Charity hospitals, often established by religious orders, were generally places to which people came to die. In the later stages of industrialization, as part of maintaining the stability and productivity of employees, medical-care programmes both in the metropolitan countries and in the third world were developed for wage earners and their families. Environmental sanitation and quarantine emerged as incipient public health programmes in the nineteenth century, and sometimes became one aspect of colonial rule. As the middle classes became more affluent, they stimulated the growth of private medicine in the West. In socialist countries, health care for the general population emerged as an important responsibility of the State.

77. Family planning as a separate preventive health service was offered before 1960 in only a small number of privately sponsored clinics. Opposition both from the medical profession, which saw only sterilization and abstinence as effective and harmless procedures, and from public officials afraid of negative reactions from Catholics, prevented the inclusion of this service in the charity medical care facilities of Western and colonial countries. Meanwhile, the middle classes in Europe and European populations overseas were able to obtain cervical caps and diaphragms from private medical doctors, and relatively safe abortions from clandestinely practising physicians. Gradually, beginning with India and Barbados, a number of countries began to provide family planning services to the masses. In many socialist countries, based on the importance given to women's rights and family welfare, abortion and contraception have been made available on relatively liberal terms.

78. The recent upsurge in concern with population growth has given a strong impetus to the further develop-

ment of family planning programmes. Too often, however, these latter-day efforts are being promoted for purely Malthusian ends, ignoring the health and welfare of the family except as part of "motivational" propaganda.<sup>50</sup>

#### *Women's liberation*

79. The distribution of power between men and women is quite egalitarian among surviving gathering-hunting societies. In independent agricultural villages, the balance shifts somewhat to favour the men, but numerous instances of matripotestal and matrilineal societies have been described. With stratification and feudalism, as mentioned above, women are firmly relegated to a subservient role. Under slavery, and in some colonial situations, women's position did not sink as low as men's, since some of them continued to work as domestics well into old age, whereas the men were required to do heavy physical labour and became less "useful" as they became older.<sup>51</sup>

80. With industrialization, women were hired in factories; however, they were paid a lower wage even if they did the same kind of work as men. Western middle-class concepts about the wife as a social ornament also worked to the disadvantage of women in the economic and judicial realms. The export of such ideas reinforced patterns from the feudal period in non-Western societies, with the result that relatively few women in the more prosperous classes consider it proper to obtain gainful employment. Thus, in India, it is the women from the lowest status groups and from the top *élite* who are most likely to obtain gainful employment, with most of those in between remaining part of the household economy.

81. Strong movements for women's liberation are emerging among the wives of the *élite* in Africa, Asia, Latin America and the Middle East. In a number of instances, as in Tunisia, attempts have been made to mobilize a wider group of women to take part in the work of the national political party. Achieving equality for women is a high-priority objective in socialist countries. In Europe and the United States of America, a new movement for women's liberation, largely based among intellectuals, has emerged within the past five years. The goals of the movement range from economic equality to emancipation from psychological feelings of ineptitude and inferiority.<sup>52</sup>

#### *New social institutions*

82. Prospects that the State will "wither away" do not look too bright at the moment. If it does so in the future, however, there will still be social institutions

through which people will relate to one another. The family, or something like it, may well be one of these institutions. There may also be, at least for a time, a world government to preside over the dissolution of States and to foster the ecological welfare of the planet.

83. One institution related to the family, which may become very important in the future, is the commune. Some communes in the past few centuries have been formed in the context of Christian religious movements, usually under the leadership of a single leader or "holy" person.<sup>53</sup> A more secular, but still slightly mystical, basis for the formation of such groups has recently been provided by the back-to-nature movement. Most Israeli kibbutzim have also been formed on the basis of a religious or a socialist ideology. Communes in the Union of Soviet Socialist Republics and other centrally planned economies are primarily an economic institution; but in some cases, they have been involved in new departures for family life as well.

84. The relationships between men and women and between adults and children are an important area in which communes tend to depart from the cultural pattern of the societies around them.<sup>54</sup> Another feature,

which in fact may be most characteristic of all communes, is the discouragement of private ownership. Since these communes arose from feudal and industrial societies, in which women and children are often treated as the "property" of the household head, communal ownership of resources and non-exclusiveness of conjugal and parental bonds can be seen as related phenomena.

85. As mentioned above, in some recently formed communes a concern for man-environment relationships ("ecology") has been an important feature. The sharing of productive resources, the low "through-put" of energy, the flexibility of sexual unions, the participation of many adults in bringing up children and the feeling of closeness to "nature" all resemble gathering-hunting societies. If communes, then, are a prototype for the small-scale institutional organizations of the future, they might also signal a cyclical or spiralling movement in history. Recalling that the gathering-hunting stage of human evolution took up most of the 2 million years since humans walked erect, a Utopian view of the future could also imply that these past 10,000 years, with the misery and oppression brought about by feudalism and market societies, represent an unfortunate detour in the course of human evolution—a detour that could have been destroyed, and still might destroy, the human species and, possibly, even the entire biosphere of this planet—but, perhaps, only an aberration that neither was necessary nor is permanent.

## DEMOGRAPHIC FACTORS INFLUENCING THE FAMILY CYCLE\*

*Mercedes B. Concepción and Felipe Landa-Jocano\*\**

1. Traditionally, demographers study population problems in terms of such individual traits as sex, age, occupation, education, religion, and so on. These factors are believed to be highly significant in understanding human fertility behaviour. There has been very little, if any, study of individuals as socializers and as active participants in group life. Equally lacking in many demographic analyses is a serious consideration of the family or household as a social unit and determinant of behaviour. While individual traits are important, the family presents a greater challenge to demographers, particularly to those involved in population control programmes. It is through the family that society is formed, each generation is replaced by another, and decisions are reached concerning care, support and responsibilities to the group. Above all, the family is central to fertility, dependency, consumption costs, savings and social welfare.

2. This paper focuses attention on the formation, development and dissolution of the family as affected by changes in demographic factors and by such environmental constraints as place of residence (rural or urban) and prevailing socio-cultural conditions. Various studies in the Philippines and elsewhere in Asia are examined to discover modal forms of adaptation to changing demographic conditions. However, in so doing, one should bear in mind that Asia is tremendously broad and subcultural variations are complex so that any general statement requires repeated qualifications with regard to points of reference which may not apply to other groups. In fact, this limitation also applies, in some way, to the Philippines. Demographic data on the national level about family formation and dissolution are meagre, although case studies are available from different communities. The life cycle of the family is apparently one of the neglected studies in the country, if not in the Asian region. These case studies are used to illustrate certain processual principles associated with family formation rather than to make generalizations about its developmental cycle in the Philippine setting and elsewhere.

### BASIC CHARACTERISTICS OF THE FAMILY AND HOUSEHOLD.

3. In any society, the family is the basic building-block of social organization; it constitutes the fundamental unit out of which the entire society is organized. And within it the total world view of the people is developed. This has been so because the family, in many respects, is the first social unit to take hold of the individual before any other agencies in the community could contribute to the moulding of his personality. An understanding of how people think of the family in various cultural settings and of the role the family plays in people's lives is crucial to any attempt at innovation, especially at community levels of action. This requirement is particularly true of population programmes wherein the innovation being introduced involves the most intimate aspect of conjugal relationship—fertility behaviour.

4. The term "family" is commonly used to refer to the social unit of society, a unit normally composed of the father, the mother and their unmarried child or children who are either adopted or biological offspring of the spouses and who are either living with them or not. In its elementary or nuclear form, the family conceptually excludes all kindred outside the conjugal, parental and filial relationships, although in actual practice other kinsmen are sometimes considered part of the unit. In its extended form, the family encompasses a wider range of bilateral relatives who may either live with the family under one roof or occupy the "next door" in a family compound or apartment. This recognition of bilateral extension of kinship includes moral obligations to support these relatives in time of need or when they are too young to support themselves at the time of residence with the family.

5. Students of different Asian societies have characterized the family into a number of types. The more conservative observers simply make distinctions between the nuclear family and the extended family types, as described above. In addition, they differentiate "family of procreation" from family of orientation. The former is Ego's own family, established by his marriage, and the latter is the unit where Ego is born. Moreover, the family of procreation is composed of the spouses and their children; the family of orientation consists of Ego's parents and siblings.

6. Other researchers have sought to describe the family in terms of the structure of the unit. Several

definitions of the nuclear family as used by different authors<sup>1</sup> contain a common element—the presence of father, mother and unmarried children. In the situation described by Bessaignet, individual relatives in the household, other than the conjugal family, were regarded merely as an “adhesion”, *ad hoc* arrangement, with the nuclear family retaining its character. The implication here is that adhesions are simply additional persons exercising a minimum of influence on the structure of relationships within the nuclear family. In the Philippines, this may be the case with domestic helpers, but not with kin relatives who normally expect to be within the immediate family circle.

7. These observations lead to the conclusion that even in a relatively simple definition of the nuclear family, the cultural overtones have to be taken into consideration if one is to grasp the full significance of the empirical referents of a concept applied in different cultural settings.

8. The elements that appear to be the characteristics of an “ideal type” extended family have been described as follows:

- “a. Relatives other than husband, wife and unmarried children sharing residence with or living adjacent to the nuclear family.
- “b. Recognition of kin relations, either of a lineal or a collateral character.
- “c. A pooling or sharing or joint ownership of resources which is usually formalized or legally recognized.
- “d. Recognized common responsibilities.
- “e. Common family or ancestor worship.
- “f. Reciprocal assistance patterns.
- “g. Joint activities either in production or consumption or both.
- “h. Maintenance of expressive relations among extended family members, such as visiting, letter-writing, etc.
- “i. Use of the extended family as a reference group in decision-making.
- “j. Authoritarian control over relationships and decision-making based on age, command over resources, etc.”<sup>2</sup>

9. In general, the classical view among students of the family is that the level of industrialization and urbanization is inversely related to the incidence of the extended family.<sup>3</sup> There is also a belief that extended families are much more prevalent in rural than in urban areas. It is maintained that the extended family tends to be replaced by the nuclear family as the society develops.

10. It had also been assumed that family size in rural, pre-industrial societies was substantially larger than that in developed countries, owing not only to higher fertility and larger numbers of living children, but to the doubling-up of nuclear families within the extended *ménage*. The notion of the typical family in pre-industrial societies was one containing representatives of three or more generations, two or more nuclear families and several collateral relatives. The traditional family in India was often cited as an illustration of this large and complex family system. Dandekar and Unde have questioned this widely held view as not being supported by empirical data.<sup>4</sup> Levy<sup>5</sup> argued that actual family structure has been rather similar in societies at all times and places, regardless of the structural ideals. Table 1 presents the extent to which one type predominates over the other in selected Asian countries. The differential incidence of nuclear and extended households in urban and rural areas in various Asian societies is shown in table 2.

11. Definitions of the extended family indicate the direction of changes occurring in the transition from traditional to modern society. Hagen viewed the extended family of traditional societies as made up of several generations in which all feel responsible for all and economic resources are pooled and made available to every member, subject to the judgment of the family patriarch.<sup>6</sup> Husain distinguished different degrees of jointness in terms of residence, consumption, participation in production, in economic decision-making and sharing of the family income.<sup>7</sup> Iijima defined the minimally extended family as consisting of the nuclear family and the parents of either husband or wife.<sup>8</sup> The

12. It is erroneous, however, to assume from the foregoing that the classical features can be found only in traditional society or that the modern elements exist only in highly developed societies. There is a tendency for the traditional and modern features of the extended family to coexist in a particular society although some elements are more characteristic of developing and less of developed societies and are more prevalent in certain countries and less in others, even within the general category of developed or developing countries.

13. What emerges from the above classification of types of families is the equation of the family with the household. Of course, the distinction is not very clear-cut. The household is composed of two or more families living in one house; the members share a common kitchen, contribute to the procurement of household necessities (except the staple grain) and prepare and eat their meals separately, and exchange cooked food. If the house happens to be a one-room dwelling, as in the village, members sleep in their chosen places. If the house is an apartment in the urban areas, members sleep in their respective rooms. Like the nuclear family, the household is a consumption unit, with a common protective roof as the unifying factor.

14. Structurally, the household is distinguished from the nuclear or extended family by its size and in some cases its membership, which extends beyond the limit of kinship. The extended family has kinship as a point of reference; a household need not have this framework. A friend or any farm-hand of good standing with the family may be taken in as a member of the household until old age. Some distant relatives are sometimes

taken in, especially unmarried siblings and cousins. In any case, the household oftentimes acts as a single economic unit in which the elementary families work co-operatively with the head of the household, who is usually either the father, the mother or one of the grandparents.

15. The composition of the household, as in the family, does not have any rigidly defined pattern. It changes as new generations of kin are born and as the circle of recognized relatives expands or contracts. The following frame of reference may be taken into consideration with respect to the structuring of the household:

(a) A newly married couple lives with either of the spouse's parents temporarily for about a year or so, until the birth of the first child;

(b) After the birth of the first child, the couple establish their own independent family, either in the vicinity or away from the family of orientation;

(c) Because both parents often work, either in the office or in the field, a close kin, usually the sibling of either spouse, or a domestic servant, stays with the children when they are away. The kin or servant may stay in the household indefinitely, as long as they are on good terms with the family;

(d) The children who marry upon attaining the right age either leave or stay with their in-laws.<sup>11</sup>

16. Like the family, the household has also been characterized into types. Nena Eslao,<sup>12</sup> in her study of a district in Manila, presented the following characteristic features of the household:

(a) *Nuclear family type*. This group consists of a respondent (R) and her spouse, with or without children (real or adopted). Any children included must be unmarried;

(b) *Nuclear-lateral*. The household has a nuclear core consisting of R's family, but which is extended by the presence of persons who are not lineally related to the respondent or her husband, and whose parents are not in the household. Unmarried siblings, children of siblings, siblings of parents or their children constitute the most common type of lateral extensions;

(c) *Nuclear-joint*. The only difference between this type and the preceding one is that at least one of the lateral extensions to the household is currently married or has had conjugal experience in the past;

(d) *Nuclear-linear*. The nuclear core is extended by the addition of one or more of the following relatives:

(i) Married children, their spouses or both, with or without children;

(ii) Grandchildren whose parents are not in the household;

<sup>11</sup> Felipe Landa-Jocano, *Growing Up in a Philippine Barrio* (New York, Holt, Rinehart and Winston, 1969).

<sup>12</sup> Nena B. Eslao, "The developmental cycle of the Philippine households in an urban setting", *Philippine Sociological Review*, vol. 14, No. 4 (1966), pp. 199-208.

(iii) Parents of the respondent and/or of the respondent's husband;

(iv) Parents and siblings (with or without spouses and children) of the respondent and/or of the respondent's husband;

(e) *Less-than-nuclear*. In this type, the respondent does not have a co-resident spouse. The category includes those households in which the female head is widowed, separated or currently married but whose husband resides elsewhere because of illness or extended employment abroad or in the provinces;

(f) *Single (R)*. This group includes all those households in which R has never been married.

17. The basis of these different classifications by Eslao is the age of the respondents at the time the family is established. It is clear that the household undergoes changes in composition over time, and it does so "in a perceptible direction". During the early stage of development, the domestic unit "tends to assume one of the three possible forms: Single-R, nuclear-lateral and nuclear joint". Sooner or later, "the female household-head marries or the extensions leave and the domestic unit, therefore, assumes an independent nuclear form". During this state, the household unit may recruit new members either by "birth and/or adoption causing the household to expand numerically while retaining a more or less permanent nuclear structure". The latter stage may be characterized by marriage of older children, in which case the nuclear core may acquire new extensions. Or it "may also lose some of its members. Old age and death eventually bring about the dissolution of the original domestic unit but the process of replacement ensures continued existence of the household beyond the life of any particular member".

#### VARIATIONS IN THE SIZE AND STRUCTURE OF FAMILIES AND HOUSEHOLDS

18. Two developments in the field of demography have contributed to the study of families and households. First, the concept of the family life-cycle was developed to serve as a frame of reference and to provide a set of definitions for comparative studies of families and households on an international scale. In essence, the concept involves the idea that families undergo a series of stages during which changes take place in family size and composition with concomitant social and economic consequences calling for adjustment on the part of the family members. Secondly, the changes in size and structure of families and households parallel the process of demographic transition in the face of modernization, industrialization and urbanization.

19. In the course of the demographic transition, certain characteristic features of households may be distinguished for each of the two major stages:

(a) Relatively constant, high fertility coupled with moderate or rapidly declining mortality;

(b) Substantial declines in fertility accompanied by further, albeit slower, declines in mortality.

20. Most developing countries in Asia are likely to be found in stage (a). The prominent features with respect to changes in family and household size and structure, according to Davis,<sup>13</sup> include:

(a) Moderate increases in average size of households and families;

(b) Moderate increases in relatively large-sized (six or more persons) households and families and moderate decreases in relatively small-sized (three persons or less) households and families;

(c) Very small increases in the proportions of heads of households for the different sex and age groups;

(d) Small increases in the proportions of nuclear families and moderate increases in the proportions of one-person households.

21. More distinct and sweeping trends have characterized developed countries which have passed through stage (b), as follows:

(a) General secular decline in the average size of household and family;

(b) Increase in proportion of small-sized (three persons or less) households and families and decreases in large-sized (six or more persons) households and families;

(c) Over-all increases in proportions of household heads specific for age and sex, except among middle-aged families;

(d) Increases in the proportion of nuclear families and one-person households and decreases in the proportion of multigenerational extended families.

22. Limited trend data on household size and composition are available for selected Asian countries. To the extent possible, the figures are recorded in table 3 in an attempt to trace the multiphasic responses of families and households to changing demographic, economic and social factors. The data on household size in Japan show some irregularities and reverses in the course of the decline, although the trend over time is clear. The gross reproduction rate of Japan declined from 2.56 persons in 1920 to 2.13 persons. It is worth noting that while fertility declined considerably during this period, average household size was increasing. Although the effect of fertility decline on reducing household size was considerable, these results imply that other forces operating in an opposite direction were stronger. There appears to be a time-lag between the initiation of declines in fertility and reductions in size of household. The forces that cancelled out the effect of fertility decline in pre-war Japan were perhaps a more significant mortality decline and the tenacity of the extended family system in some sectors of the society.

<sup>a</sup>Data refer to Republic of Korea.

23. For the past 60 years, India has shown a relatively stable average household size, although recent increases have been noted. The data argue against the commonly held notion that the joint family prevailed in the past. Dandekar and Unde<sup>14</sup> maintain that declines in mortality have led to increases in Indian household size. The same trend was observed for Korea.

24. Rapid declines in mortality in the absence of substantial fertility declines, such as those occurring in most of the developing Asian societies, have been

<sup>14</sup>Dandekar and Unde, *loc. cit.*

causing increases in family and household size in the Philippines. It may be expected that these increases will halt eventually, and family size will begin to decrease after fertility declines have overtaken mortality declines. According to Burch, "a rise in the average household size could occur as an early response to modernization simply because of the rise in the average number of surviving children. One would expect family size to decline again as the level of fertility falls in response to lower levels of mortality and changed living conditions".<sup>15</sup> The demographic transition is likely to have its parallel in family and household structure.

25. Burch,<sup>16</sup> in investigating the influence of demographic variables on average household size under different family systems, found that under all family systems average household size was positively correlated with fertility, life expectancy and age at marriage. His stable population approach had been applied earlier by Coale<sup>17</sup> to stationary populations. Households under nuclear systems never exceeded 10 persons, on average. By contrast, under extended-family systems, with low mortality and high fertility, average household size reached levels seldom if ever observed in real-life situations, e.g., 25 persons per household.

26. Burch's hypothesis is unsupported in Asian countries, where positive relationships could only be found between average size of household and fertility. For other measures listed in table 4, inverse relationships held for average size of household with age at marriage and with life expectancy.

27. The importance of marriage and marital status as factors influencing the size and structure of house-

holds and families has been widely documented by demographers and sociologists. Marriage constitutes the first step in the formation of the biological family, and the time most newly-wed couples establish their own households determines the extent of nuclear households.

28. In the post-war period, the trend observed in developing countries was towards later marriage. For example, the mean age at marriage in the Philippines rose from 20.9 years in 1903 to 22.3 in 1960.<sup>18</sup> By comparison, much larger changes occurred in India<sup>19</sup> and the Republic of Korea.<sup>20</sup> The process of modernization and industrialization in the developing countries can be expected eventually to bring about further substantial changes in marital status by age which will produce important effects on average family and household size.

29. Changes in the proportion of other marital-status groups besides the "married" also have an important bearing on the size and structure of families and households. In developing countries, where earlier marriage prevails, single persons at adult ages are relatively numerous. In addition, there is a much larger percentage of widowed persons, particularly among females in the older ages, owing to higher mortality (see table 4). Increases in the proportions of widowed and divorced female population generally produce a greater number of household heads that are female and contribute to a shrinkage in the average size of households.

30. Another factor that tends to influence household composition is the age of the household head. The number of Philippine households with non-nuclear members tended to increase with the age of the household head, as recorded in table 5. These Philippine findings are consistent with those of Yomina Talmon<sup>21</sup> in Israel, where children who have grown up are expected to live

in the community founded by their parents in order to provide geographical proximity and daily face-to-face contact with aging parents. When the Filipino respondents were asked where they expect to obtain support in their old age if they have no savings, 16 per cent mentioned relatives as a possible source. In other words, old people in the Philippines, as elsewhere, turn to the extended family for companionship as well as for other needs in their old age. These findings likewise support the notion of a development cycle through which a simple family grows into an extended one and then breaks up into a simple family again. In India according to S. C. Dube:

"... a simple family emerging from this process may retain some adhesion or adhesions from the former extended family. Aged parents may later attach themselves to one of their sons who had broken away from the parental home earlier to set up an independent household. The changes from simple to extended and from extended to simple families are fairly frequent. Perfect three-generation extended families are rare, and not many simple families can remain technically simple for a long period."<sup>22</sup>

31. In a study of residence<sup>23</sup> in Canaman, Camarines Sur, Philippines, the following six decades in the developmental cycle of household arrangements are identified:

*First decade* (15-24), when most children are still members of the parental unit and household;

*Second decade* (25-34), when an increasing number of subordinate units are gaining independent status;

*Third decade* (35-44) and *Fourth decade* (45-54), when a drop occurs in the proportion of independent nuclear units being created; in the fourth decade, children have usually moved out of the parental household and the independent married-couple household emerges;

*Fifth decade* (55-64), when there is an increase of dependent units;

*Sixth decade* (65 and over), when the number of dependent units reaches a peak.

32. This characterization of the developmental cycle of the household is supported by Agaton Pal's data in the Visayan region, Philippines.<sup>24</sup> On the basis of age structure of husbands and wives relative to the dependency of the parents, he states that between the ages of 35 and 44 the dependency burden is highest. From 45 to 64, the dependency burden declines due to two factors: the wife stops giving birth; and some of the children are old enough to assist the parents. Lastly,

TABLE 5. PHILIPPINES: AGE DISTRIBUTION OF HOUSEHOLD HEADS, BY HOUSEHOLD STRUCTURE, 1968

Age of household head (years)	Household structure	
	Nuclear	Extended
	(percentages)	
15-34	27.9	19.1
35-49	42.7	29.3
50-64	22.8	34.1
65+	6.6	17.5
TOTAL	100.0	100.0

SOURCE: Alice C. Lim, "Comparative study of nuclear and extended households in the Philippines", unpublished Master's thesis, University of the Philippines, 1973.

from 65, the dependency burden begins again. As the family dissolves, the household expands.

33. The markedly different patterns of family life cycles in the two countries, shown in table 6, show the influence of demographic and cultural conditions. India shows an early marriage of women, an early bearing of the first child, a long childbearing period and a lengthy period during which the children remained in the parental household. Moreover, the data for India show that a mother is likely to live as a widow for more than 10 years before the marriage of her youngest child.

TABLE 6. INDIA AND JAPAN: MEDIAN AGE AT DIFFERENT STAGES OF THE FAMILY LIFE CYCLE (Years)

	Banares, India, 1956		Japan, 1960
	Husband	Wife	Wife
First marriage	17.3	14.6	24.4
Birth of first child	20.9	18.2	26.3
Birth of last child	39.7	37.0	28.7
Marriage of first child	36.9	34.2	—
Marriage of last child	55.7	53.0	54.5
Death of one spouse	42.2	39.5	69.1
Age at own death	54.4	54.5	—

SOURCE: For India, Andrew Collier, "The family cycle in India and the U.S.", *American Sociological Review*, vol. 28, No. 1. (1963), pp. 86-96; for Japan, Kiyomi Morioka, "Life cycle patterns in Japan, China, and the United States", *Journal of Marriage and the Family*, vol. 29 (August 1967), p. 605.

34. The family life cycle of Japan is characterized by late marriage and birth of first child, and by a surprisingly early termination of childbearing. In fact, childbearing is concentrated in a very short period of 2.4 years, since the first child is born on average when the mother is 26.3 years of age and the last is born at age 28.7. In contrast, the Banares, India, data show the average childbearing period extending over 18.8 years. Also, owing to the substantial increase in longevity among men as well as women in Japan, a parental couple can expect to live together for almost 15 years after the last child has married and set up his own household.

35. The apparently traditional descriptions of the family and household presented above must not mislead one to think that there are no variations in both the structure and the function of the family and household. Indeed, variations are numerous. The types of families and households found in the rural areas and the roles they play in community life are certainly different from those found in the urban areas, especially in suburban residential locations. But when the basic characteristics—the unquestioned, implicit postulates—are examined, far greater similarities than differences stand out. In both urban and rural areas, the family functions as the main point of reference in the various networks of social relations, a reservoir of values and norms that legitimize

much of interpersonal and group behaviour in the community.

36. Seen in the prevailing emphasis on emotional security, economic support and kinship loyalties, it is understandable that any deliberate attempt at changing the structure of the family will inevitably meet with some kind of "resistance"—explicitly stated or implicitly enacted. The change in structure would mean a change in content of interpersonal relations within the family, and this would undermine the existing pattern of cultural behaviour.

#### FAMILY SIZE AS AN ECOLOGICAL RESPONSE

37. Reliance on the family for the resolution of major economic and social problems is, perhaps, the main reason why most Asians have large families, in spite of verbalized preference for small ones. Available literature has indicated the range to be from five to seven children, with variations from eight to ten.

38. In some countries, particularly in the urban middle-class communities, the sizes range from three to five. On the whole, large family sizes are maintained in the face of great efforts to reduce them. Available data suggest that family and household sizes can be seen as ecological responses to place of residence.

39. For example, in nine studies dealing with the Asian family, seven of them showed the prevalence of nuclear families (see table 1). Although there was some indication that extended households occurred in the urban areas, the extensions do not always rest on kinship ties. This is understandable because working parents generally hire domestic help to attend to household chores while they are at work.

40. In one report,<sup>25</sup> two explanations are given as apparent reasons for the trend towards extended households in the urban areas:

(1) The possibility of urban families being economically better off than rural relatives and the tendency for kinsmen to gravitate towards the more affluent members;

(2) The possible flow of rural family members to the urban areas to study or work, in which case they seek their kinsmen and join their household.

41. Internal migration has a very important impact on household size, particularly in rapidly urbanizing countries, such as Japan. The significance of this factor lies in the fact that massive internal migration can lead to the formation of nuclear households or undoubling of families, even in a country where the nuclearization process is otherwise rather limited owing to deep-rooted extended-family traditions.

42. Migration of single persons to urban areas often works in two ways towards a decline in average house-

<sup>25</sup> John J. Carroll and others, "Provincial paper on changing patterns of social structure in the Philippines, 1896-1963", United Nations Educational, Scientific and Cultural Organization, Research Centre, 1963.

hold size, first, by reducing the size of the parents' households; and, secondly, by increasing the proportion of small-size households in the area of in-migration.

43. Migration is nearly everywhere highly selective, and migrants consist predominantly of young adults. A great number of young migrants to urban places live in boarding-houses or one-room apartments, thus forming either one-person households or else becoming part of group quarters or institutional households. The formation of many new small-size households in urban areas, concomitant with internal migration, clearly contributes to lower average household size both in cities of in-migration and in countries or villages of out-migration. In Japan, it was found that about 27 per cent of the decline in average household size between 1955 and 1965 was due to the formation of new one-person households, as a result of internal migration. On the other hand, a dramatic decline in single-person households in Singapore (from 20.7 per cent in 1957 to 8.2 per cent in 1966) contributed to the rising average household size.

44. In the course of the family cycle, improved economic and social opportunities in urban areas may induce the husband or couple to migrate, thus bringing about changes in average family size and composition, and possibly even in the eventual number of children born to the couple. At the other end of the family life cycle, it is frequently common, particularly in developing countries, for elderly couples to return to their villages of origin to spend the last years of their lives, after residing in the town or city during their reproductive years and bringing up their children there.

45. Nevertheless, smaller families are unmistakably more prevalent in the urban-industrial and high-income countries than in the rural-agricultural and lower income countries. This situation is due in part to the fact that the urban-industrial countries are characterized by low fertility, whereas the rural-agricultural countries have unequivocally high fertility. Moreover, in urban-industrial countries, there is generally a greater tendency for grown children to leave their parental households early and for older persons to retain their own households than is the case in rural-agricultural countries.

46. Various economic changes associated with the process of industrialization may exert an influence on household size. While the participation of women in economic activities may have an influence on household size, the nature of this relationship is not entirely clear. On the one hand, high activity rates for women, through their effect in lowering fertility, may tend to reduce average household size. On the other hand, it has been argued that high female-activity rates can lead to a slowdown in the process of household fission and to a renewal of the functions of the doubled-up family. Empirical data on this question are presented below.

47. Seen in this perspective, it is clear that attempts at deliberately restructuring the size of the family are fraught with difficulties because the rationale for

maintaining large families is more attuned to the adaptive needs of the members in the context of the socio-economic *milieu* of the community. By "adaptive" is meant the capacity of an individual or unit to maintain life in a particular habitat. In the rural areas, the economic potentials of children and the assurance of early relief from the burden of work on the part of parents function as ecological pressures to which farmers respond accordingly. The same requirements are imposed by the urban environments on urban dwellers. The potential assistance of the successful kinsmen in the urban areas serve as a stimulus for urban migration and eventual extension of households. The high cost of housing in urban areas also functions as an environmental constraint for people to live together under one roof. There is no such pressure in rural areas.

48. Thus, the argument that the target population must limit the number of children because the people are hit hard by economic problems does not appeal to many in the so-called "disadvantaged areas" because it neglects the fundamental requirements of adaptation.

49. Perhaps a few illustrative cases from the rural and urban areas in the Philippines will further help to clarify the above-mentioned points on adaptation. In the western Visayas and in the Laguna Lake area, available data indicate that the average sizes of families in communities studied ranged from five to seven children. Interviews with parents concerned revealed that they recognized the difficulties accruing from having more children than they could economically support. At the same time, however, they enumerated the advantages of large families which, when compared with perceived difficulties, outweigh the difficulties in terms of fulfilling much of the adaptive requirements for economic survival and psychological needs. In effect, the contribution children will make to the family larder in future is part of the traditional, un verbalized family planning strategies of many target populations, and this factor reinforces the need for larger families.

50. The same is true with respect to slum-dwellers. In fact, one more factor may be added—the high rate of illegitimacy. This phenomenon may be attributed to the impersonality of urban environment, where strict moral values, in terms of stigma the community attaches to deviants, are dysfunctional; to the greater emphasis on the *machismo* complex among males; and also to the need for economic and psychological support among females. All of these factors add up to impose certain pressures on the people to behave the way they do, which contributes to the increase of childbirth.

51. The *machismo* complex, for example, imposes on an individual the need to engage in a sexual role which could only be verified by the peer group to which he belongs in terms of the number of affairs he maintains and the number of children he sires either with his legitimate wife or with his mistresses. In fact, it is not surprising to find a labourer or omnibus driver, barely earning \$50 a month, having two or three mistresses. For a woman, having children also means

an additional source of income. It is a dominant belief among informants that a man may not support his mistress, but he can be coerced into supporting his children. Moreover, most female informants are unanimous in their belief that "being a mistress is a temporary affair wherein youth is dissipated in the process. Without a child or children, one is in a pitiable situation in old age." In effect, this view supports the adaptive requirements of slum life.

52. Preference for large families is not only the core value of the above-mentioned disadvantaged groups. Civil organizations and educated leaders in many countries in the region almost "hero-worship" large families by giving annual awards to "Family of the Year", "Parents of the Year", "Outstanding Parents" and so forth. Although the awards are generally focused on achievements of members of the families selected, the sacrifices parents experienced in the process of bringing up a large family are publicly recognized and extolled as virtues to be emulated. Faced with this public adulation of large families, it is doubtful whether small ones have any virtue at all. As the "rewarding ritual" becomes an annual affair, it likewise becomes part of the aspirations of most people: a perceptual model towards which efforts have to be geared if only to gain public recognition. Implicitly, acceptance is a powerful stimulus for achievement-motivation; and, if the society places a high premium on big families, then the acceptance-goal of people will certainly be directed to this end.

#### FAMILY SIZE AS A CULTURAL RESPONSE

53. The persistence of large families in both rural and urban communities studied in the Philippines led to an inquiry on the meaning of family size to the people. It is, perhaps, in the perceptual domain of target populations that one could find clues for a satisfactory explanation of this phenomenon. In the search for models, however, some difficulties were encountered. No consensus could be obtained among informants with respect to the most preferred norm for family sizes. What they verbalized contrasted with what they had in terms of family size. Even those who had aspired to smaller families during the early stage of their marriage in 1964 were today burdened with large, growing ones. In other words, certain factors must have come into play, other than biological determinants, which earlier aspirations indicated.

54. In the Laguna Lake area in southern Luzon, levels of aspiration were inconsistent with actual numbers of children borne. The area has been one of the most worked-over areas in terms of family-planning education programmes. In addition to using broadcast and print media, the promoters of the programmes have conducted personalized campaigns for the reduction of family size. This goal seems far from having been achieved.

55. In order to specify what cultural factors might be related to family size, an attempt was made to probe into the cognitive domain of the local culture. It is interesting to note that in both rural and urban sectors of the country, the people do not have a specific term for "smallness" when referring to family units. Among the Tagalogs, terms like *kaunti* (few), *ilan* (several), *maliit* (small) and similar diminutive terms and phrases are used to place emphasis on "smallness". However, the usage is more analogous than specific. *Maliit na pamilya* (small family) is applicable but does not necessarily describe the actual size of the unit because the term *maliit* emphasizes smallness with reference to individuals or physical entities, as in *batang maliit* (small child). In fact, when the phrase *maliit na pamilya* was repeated to a number of informants, corrections were offered because it was said that the phrase did not quite sound right.

56. On the other hand, the term for "large size" is precise—*laki*. This is generic. Even in asking questions, the correct phrase is, "*Gaano kalaki ang inyong pamilya?*" ("How large is your family?") Smiles and expressions of "ahs" were registered on the faces of those present in the interviews when an informant stated that they "have a limited number of children". Many informants who only have one or two children are often teased; in the judgement of others, they are either sterile, weak or simply stingy; and "what a pity for the child—no playmates".

57. In other words, the concept of smallness as part of the family attribute is not present in the folk culture of the communities studied. In contrast, largeness in family size is the ideal type, and hence it is sustained by the perceptual categories present in the cognitive domain of the people. To stress over and over the need for a small-size family or to emphasize it as desirable is to expect certain misconceptions concerning the innovators' motives since there is no point of reference in the culture to support the new idea.

#### IMPLICATIONS FOR POPULATION EDUCATION STRATEGY

58. Proponents of small-size families always point to the achievement of western societies as desirable models. There is no quarrel about this. The main question is how western societies achieved the shift and whether it is possible to replicate their experiences in non-western societies, such as those found in Asia. The answer is "yes", provided the ecological conditions which brought about the shift in western societies are also replicated. Again, one has to look at the adaptive requirements of environment which will sustain the change once it is introduced.

59. It is, perhaps, safe to say that one of the pre-conditions for the reduction of family size to a desired number is ecological change. Industrialization is one such change which is necessary for sustained familial change. For a model, one has to examine the conditions

in industrial communities, or even in the suburbs, of Asian cities.

60. In a suburb of metropolitan Manila, for example, data indicated that as income increased, due largely to the construction of seven factories in the community, housing and job shortages decreased. To the working families concerned, household help became a necessity, just as staple food was.

61. Working couples had to make certain decisions concerning the number of children. Either the wife quit her job or a domestic helper was hired. In the latter case, it meant additional family expenses in terms of the helper's salary; if the choice was the former, it also meant reduction of income. Most couples resorted to spacing of children. And while it is true that urban families tend to be larger than rural ones, the extension is often defined in the context of business transactions. That is, the kinsmen who join the nuclear family, except siblings, often pay board and lodging; sometimes, the payment is in the form of rice, vegetables and other staples.

62. In other words, it is generally the ecological pressure which generates change and gives it direction. As was noted, the place of residence influences the formation, growth and dissolution of families. As one moves from the rural to urban areas, the change in the size of families—from nuclear to extended—is very remarkable. In the rural areas, nuclear families are easily established if only for the reason that one can build his own house, however light the materials used. The space is open. No one pays rent; and, in some cases, one does not even have to ask permission. In contrast, extended families are dominant in the urban areas, particularly in the slums, because of the high rent, shortage of housing and temporary nature of residence in one place.

63. Thus, even if the programme on population education is understood but local resources cannot sustain it, its implementation is likely to encounter some difficulties, if not outright rejection. This is perhaps one of the reasons why family planning programmes, despite the energy expended on them in terms of education and training of promoters of change, only achieve a very minimal effect. On the basis of available data, it can be predicted that without the corresponding ecological support in terms of community resources, the problem of population increase in the Philippines, as well as in other Asian countries, is likely to persist for a long time.

64. Family planning innovation is similar to other kinds of change. It has to be maintained at the community level of action. In the field of economic change, for example, innovators have been sponsoring the idea that education is the answer to the problem. However, many have not quite realized that decision-making in this connexion is a painful process. The parents have to decide between making the child contribute to the eco-

nomical larder early or to delay his earnings by furthering his education. Often the former triumphs. The child, as soon as he is able, takes a job and contributes to the economic life of the entire family.

65. From the discussion presented above, it is clear that to anticipate or even suggest criteria for a desirable norm for family size in the region is difficult. It is even more difficult to describe it. Research data from the different Philippine communities, as well as those gathered in various Asian countries, indicate that family formation is a response to ecological pressures and to prevailing socio-cultural conditions. It is in this area that information is lacking. More research is needed on non-demographic factors which impinge upon the formation, development and dissolution of families. To state any categorical number as the desirable size for a family without seriously considering the ecological conditions which define it is to be unrealistic; it shows unfamiliarity with realities of community life. Unlike any other form of innovation, family planning cannot be shown by a positive demonstration that small families are better than large ones. For one thing, it is difficult to show empirically that better health, better levels of living, better education, better employment and so on are the resultant effects of small families.

66. Moreover, norms are difficult to specify. Even informants themselves find it hard to make familial norms explicit. There are several reasons for this problem. On the whole, the difficulty rests on the context and situation. People are reluctant to generalize when asked direct questions about norms, although they make many implicit generalizations when talking spontaneously. What emerged from research undertaken in this area was that one person's norm is not necessarily another's. Certainly, the manner in which large families succeed in business cannot be used to suggest large families for lower class, low-income families, and vice versa.

67. To say, therefore, that small-size families are desirable is to say nothing about the circumstances which may make this possible. Even the term "average" as generally applied to the family is a misnomer. It can be used to describe almost anything. Statistically, it simply defines a consistent clustering of numbers at a given point in time. However, it does not mean that culturally this enumerated response pattern is the preferred value, so that once the average index is obtained, strategies for maintaining the desired norm can be developed. As William Goode said, "Conception is an intimately personal matter, not a mass phenomenon."

68. In other words, in order to achieve a more meaningful approach to population problems, other methodologies in addition to purely demographic ones have to be used. The study of the family life cycle and familial responses to different ecological settings may furnish more insights than is usually conceived.

## THE EFFECT OF MODERNIZATION ON FAMILY REPRODUCTIVE BEHAVIOUR \*

Richard A. Easterlin \*\*

1. This paper analyses the nature and causes of the change in family reproductive behaviour associated with modernization. The first section takes up the meaning of modernization and describes the changes in family reproductive behaviour associated with it. The second presents a theoretical framework for analyzing the determinants of reproductive behaviour. In the third and fourth sections, this framework is used to trace the causal links between modernization and reproductive behaviour.

### NATURE OF CHANGES IN FAMILY REPRODUCTIVE BEHAVIOUR DURING MODERNIZATION

2. Modernization is the transformation in economic, social and political organization and in human personality observed in a growing number of countries since the mid-eighteenth century.<sup>1</sup> On the economic side, this transformation involves a sustained rise in real output *per capita*. It encompasses wide-ranging changes in techniques of producing, transporting and distributing goods, in the scale and organization of productive activities, and in types of outputs and inputs. It embraces major shifts in the industrial, occupational and spatial distribution of productive resources and in the degree of exchange and monetization of the economy. On the social and demographic side, it involves significant alterations in fertility, mortality and migration, in place of residence, in family size and structure, in the educational system and in provision for public health. Its influence extends into the area of income distribution, class structure, government organization and political structure. In terms of human personality, modernization involves an increased openness to new experience, increased independence from parental authority, belief in the efficacy of science and ambition for oneself and one's children.<sup>2</sup>

3. The changes in family reproductive behaviour associated with the process of modernization encompass actual fertility, techniques of fertility control and desired fertility. The present discussion is confined to married women, since the concern is with reproductive behaviour of the family. The presentation is partially speculative, since the evidence available on some of these aspects of reproductive behaviour is thin; but it appears desirable to try to draw as comprehensive a picture as possible, so as to identify needs for knowledge, as well as clearly established facts.

### Fertility decline

4. The change on which the greatest agreement exists is the shift in fertility from high to low levels which, together with a similar (and usually prior) movement in mortality, is termed "the demographic transition". Viewed against the long backdrop of prior human experience, the magnitude of this fertility change is remarkable indeed, as is made vividly clear in the words of one commentator on the English fertility decline:

"The typical working class mother of the 1890's, married in her teens or early twenties and experiencing ten pregnancies, spent about fifteen years in a state of pregnancy and in nursing a child for the first years of its life. She was tied, for this period of time, to the wheel of childbearing. Today, for the typical mother, the time so spent would be about four years. A reduction of such magnitude in only two generations in the time devoted to childbearing represents nothing less than a revolutionary enlargement of freedom for women."<sup>3</sup>

### Conscious regulation of fertility

5. Some writers, most notably what might be termed "the French School", emphasize an additional feature of modernization of family reproductive behaviour, namely, the mode of fertility regulation.<sup>4</sup> These scholars

(Continued on next page)

see a shift from a situation in which fertility is controlled through various social and biological mechanisms to one of deliberate limitation of family size by individual households. The view is clearly expressed by Bourgeois-Pichat:

"Fertility in preindustrialized societies seems to be strongly determined if not controlled in the sense we give to this word today. It is determined by a network of sociological and biological factors and when the network is known, the result can be predicted. Freedom of choice by couples is almost absent. The couples have the number of children that biology and society decide to give them."

"One of the main features of the so-called demographic revolution has been precisely to change not only the level of fertility but also change its nature. Having a child has been becoming more and more the result of free decision of the couple. And this change in the nature of fertility may be more important than the change in its magnitude. Fertility has left the biological and social field to become part of the behavioural science."

"For fertility we had for a long while a lot of customs carefully molded in the course of time which almost completely determined the size of families. These customs are still there but they are for the most part useless, as fertility is now under the will of people."<sup>5</sup>

6. In a similar vein, a recent paper by K. Srinivasan speaks of a "transition" in fertility regulation accompanying the demographic transition: "Every population undergoing a demographic transition also experiences a transition in the nature by which it regulates fertility . . . The stages of transition of fertility regulation methods can conveniently be classified into phases: Biological, Natural, Premodern, and Modern."<sup>6</sup>

7. It should be recognized that such statements are primarily hypotheses rather than assertions of fact. The extent to which there exists conscious regulation of fertility by individual households in pre-modern societies is a matter on which much more research is needed.

8. As the Bourgeois-Pichat quotation indicates, to some observers the change in the mode of fertility regulation is even more significant than the decline in fertility itself, because of the fundamentally new attitudes it entails. It is noteworthy that Inkeles identifies as first among "personal qualities which . . . may validly

Figure I. Stages in reproductive behaviour during modernization

Legend  
 P = reproductive potential  
 N = natural fertility  
 B = actual fertility  
 R =  $N - B$  = conscious fertility control ("births averted")

 X =  $B - D$  = excess fertility

be described as fitting a reasonable theoretical conception of modern man [that of] openness to new experience, both with people and with new ways of doing things such as attempting to control births".<sup>7</sup>

9. There are, then, two generalizations concerning the modernization of reproductive behaviour, one stressing the shift to low fertility and another emphasizing, in addition, a new mode of fertility regulation, adoption of deliberate control by individual households. Figure I (a) brings out the relationship between the two. In the figure, the degree of modernization is measured along the horizontal axis.<sup>8</sup> Following Sauvy,<sup>9</sup> the following definitions are made:

(a) Reproductive potential, *P*, is the number of children that 1,000 married women "in the most favour-

XXII, No. 2 (January 1974), pp. 320-337.

<sup>9</sup> A. Sauvy, *op. cit.*, p. 348.

able conditions" would have during their reproductive career;

(b) Natural fertility,  $N$ , is the number of children per 1,000 married women during their reproductive career if no conscious effort were made to regulate fertility.

In any society at a given time, even though no conscious effort is made by individual families to limit fertility, actual fertility will fall short of reproductive potential because of physiological conditions limiting fertility, such as malnutrition; or cultural circumstances, such as an intercourse taboo, which have the unintended effect of lowering fertility. Natural fertility,  $N$ , is therefore represented in figure I (a) as lying below reproductive potential,  $P$ , the difference being due to conditions which from the point of view of the family unintentionally depress fertility. For simplicity,  $P$  and  $N$  are assumed in this section to remain constant throughout the course of modernization.

10. The conditions envisioned in the Bourgeois-Pichat quotation imply that actual fertility,  $B$ , would be the same as natural fertility,  $N$ , in a pre-modern situation, as there is no deliberate control of fertility by the individual family. At some point in the course of modernization, depicted here as  $h$ , actual fertility begins to trend downward as individual households begin to consciously control fertility. To the right of point  $h$ , the vertical distance,  $R$ , between  $B$  and  $N$ , represents conscious fertility control, measured in terms of births averted. The diagram thus depicts a shift from pre-modern conditions, in which observed fertility corresponds to natural fertility, to modern conditions, where the spread of conscious fertility regulation is associated with a down-trend in observed fertility.

11. The purpose of the diagram is to give a schematic representation of the general trends in fertility and fertility control envisioned in the studies previously cited. A more realistic picture would take account of the marked fluctuations characterizing fertility both in pre-modern and modern times, and especially in the former. One might allow, too, for the possibility of some conscious fertility regulation, even in pre-modern conditions, among, say, the upper social strata, by allowing  $B$  to parallel  $N$ , but at a lower level. The modernization of reproductive behaviour would then take the form of the diffusion of conscious control throughout the remainder of society.

#### *Desired fertility*

12. In going beyond the fertility decline to the shift to conscious fertility regulation, one has already ventured into somewhat speculative ground. Two additional hypotheses of even a more speculative nature may be noted. One relates to the trend, not in observed fertility, but in desired fertility. Unfortunately, there appears to be little or no evidence on the secular trend in desired fertility during the history of the developed countries, and one must rely on comparing countries at different levels of modernization at the current time.

13. According to Ronald Freedman, people in pre-modern societies today typically have a fairly clear idea of how many children they would like to have:

"In various underdeveloped societies, a large number of sample interview surveys have been made since the Second World War in which peasant populations have been asked such questions as how many children they want for themselves, how many are right for others, etc. In almost all of these studies only a small minority of the respondents found the questions ridiculous or meaningless or answered that such matters were up to fate or God, etc. Even where the answers invoke the Diety or fate, further inquiry frequently indicates that the respondent has rather firm ideas of what he desires that fate or divine providence should bring."<sup>10</sup>

14. Tabbarah's survey<sup>11</sup> of the available evidence indicates that desired family size in the currently less developed areas ranges from a little over three up to eight, whereas in developed countries the range appears typically to be between two and three. If cross-section evidence on the association between desired fertility and modernization may be used to infer historical trends, then this implies that desired size decreases in the course of modernization.

15. Typically, desired fertility in developed countries lies below actual fertility, that is, there is "excess fertility". In figure I (b), a curve representing desired fertility,  $D$ , has been added to the situation depicted in figure I (a). This curve lies below the curve for actual fertility,  $B$ , and trends downward. At any given time, the excess of actual over desired fertility is excess fertility,  $X$ . Because of lack of evidence, the curve for desired fertility is omitted from the pre-modern phase of the diagram.

#### *Types of conscious fertility control*

16. The other speculation relates to whether there are systematic trends during modernization in the specific forms taken by conscious fertility regulation. In terms of the diagrammatic analysis, the question at issue relates to the importance of various components of  $R$ , births averted. This can be illustrated by reference to Requena's analysis of experience in Chile.<sup>12</sup> Still another view is presented in Srinivasan's analysis.<sup>13</sup> In Requena's model, a society passes through three stages, from no birth prevention, to primary reliance on abortion, to major reliance on contraception, with some residual abortions to meet contraceptive failure. The

Freedman, eds., *Fertility and Family Planning: A World View* (Ann Arbor, University of Michigan Press, 1969), pp. 478-489.

<sup>13</sup> K. Srinivasan, *loc. cit.*

hypothesized sequence of change in conscious fertility control is illustrated in figure I (b). To the right of point *h*, as conscious control (*R*) emerges and grows, it takes first the form of induced abortion. Eventually, however, contraception takes over and induced abortion recedes in quantitative importance.<sup>14</sup>

#### Summary

17. The picture that emerges of the changes in family reproductive behaviour during modernization is as follows: a decline in observed and desired fertility and a growth in deliberate fertility control by the individual household. In this paper, these will be taken as the "facts" of change in reproductive behaviour. An adequate explanation of the modernization of reproductive behaviour should account for all of these changes, not just for fertility decline. The growth in conscious fertility regulation may itself be marked by a characteristic trend in methods used, from, say, induced abortion to contraception, or more generally, from traditional to modern methods, but no analysis of this topic is attempted here.

18. The need is obvious for more empirical research to test out the patterns sketched in figure I, and, to the extent they prove valid, to fill in specific numerical co-ordinates. At the current time, even the facts of the decline in fertility itself are not adequately established,<sup>15</sup> let alone those in the other variables, though some recent research on natural and desired fertility is available. Naturally, the current experience of less developed countries and primitive societies provides an invaluable laboratory for this work.<sup>16</sup>

<sup>14</sup> The present diagram is a variant of that presented in the useful Population Council summary of findings from family planning research. J. A. Ross and others, "Findings from family planning research", *Reports on Population/Family Planning*, No. 12 (October 1972), p. 36. Other reports providing valuable data on fertility and fertility control in the third world are B. Berelson, "KAP studies on fertility", in B. Berelson, ed., *Family Planning and Population Programs: A Review of World Developments* (Chicago, University of Chicago Press, 1966), pp. 655-668; R. J. Lapham and W. P. <sup>16</sup> Recent years have witnessed increasing attention by anthropologists to the formal demography of primitive societies, e.g., M. Nag, *Factors Affecting Human Fertility in Nonindustrial Societies: A Cross-cultural Study* (New Haven, Connecticut, Yale University Press, 1962). In terms of the present

19. This section develops briefly a formal framework for fertility analysis, which parallels in general form the conceptual scheme of figure I and which thus lends itself to interpretation of the changes presented there. The framework is a modification of the usual economic framework for fertility analysis to take fuller account of the theoretical and empirical work of demographers and sociologists. The principal dependent variable is the total number of surviving children of a "representative" married couple, since surviving descendants, rather than births as such, are what parents are basically concerned about. Both spouses are assumed to live throughout the reproductive span of the wife. Questions relating to the formation of reproductive unions and to child-spacing are left aside.<sup>17</sup>

20. The determinants of fertility are seen as working through one or more of the following:

(a) The demand for children, the number of surviving children parents would want if fertility regulation were costless;

(b) The potential output of children, the number of surviving children parents would have if they did not deliberately limit fertility;

(c) The costs of fertility regulation, including both subjective (psychic) costs and objective costs, the time and money required to learn about and use specific techniques.

#### Demand for children

21. The immediate determinants of the demand for children are income, prices and tastes.<sup>18</sup> The demand for children is seen as depending upon the household's balancing of its subjective tastes for goods and children against externally determined constraints of price and income in a way that maximizes its satisfaction. Variations in the basic taste, price and income determinants will cause differences in demand among households at a given time, or for a given household over time. Other things being constant, the number of children desired

framework, these societies lie to the left of point *h* in figure I(b). An important contribution of anthropological research would be to establish the relative values of *P*, *N*, *B* and *D*, as well as the specific mechanisms by which *N* is kept below *P* and, if applicable, *B* below *N*.

<sup>17</sup> The present exposition is highly condensed. For fuller treatment, see R. A. Easterlin, "The economics and sociology of fertility: a synthesis", prepared for the Seminar on Early Industrialization, Shifts in Fertility, and Changes in Family Structure, held at the Institute for Advanced Study, Princeton, New Jersey, 18 June-9 July 1972; R. A. Easterlin, "Towards a socioeconomic theory of fertility: a survey of recent research on economic factors in American fertility", in S. J. Behrman, L. Corsa and R. Freedman, eds., *Fertility and Family Planning: A World View*, pp. 127-256.

<sup>18</sup> G. S. Becker, "An economic analysis of fertility", Universities-National Bureau Committee for Economic Research, *Demographic and Economic Change in Developed Countries* (Princeton, New Jersey, Princeton University Press, 1960), pp. 209-231; R. A. Easterlin, "Towards a socioeconomic theory of fertility . . ."; H. Leibenstein, *Economic Backwardness and Economic Growth: Studies in the Theory of Economic Development* (New York, John Wiley and Sons, Inc., 1967).

would be expected to vary directly with household income (assuming children are a "normal" good), directly with the price of goods in relation to children, and inversely with the strength of tastes for goods in relation to children. It is through tastes or subjective preferences that attitudinal considerations stressed by sociologists operate, such as norms concerning family size and the "quality" of children, i.e., standards of child-care and rearing.

22. As stated above, the principal dependent variable here is surviving children, since what parents are ultimately interested in is grown offspring, not number of births. Birth behaviour may be linked to the demand for children through the rate of infant and child survival. For households to achieve a given number of surviving children, the necessary number of births would be higher, the lower the level of infant and child survival. Even though tastes, prices and income remained unchanged, birth behaviour might vary because of changes in the survival prospects of children. Other things being equal, the higher the survival prospects, the lower the birth rate.

23. So far it has implicitly been assumed that the family size decision refers to children of a standard "quality", that is, children embodying a given set of inputs of time and goods. Allowance can be made for variations in child quality by viewing child quality as an additional good along with number of children and goods consumed by the parents.<sup>19</sup> An increase in income would then be expected to raise both the number of children and the standard of child quality, while a rise in the relative prices of inputs required for children would lead to substitution against both child numbers and child quality. Furthermore, subjective preferences relating to child quality might change, leading, for example, to greater emphasis by parents on the quality of children at the expense of number of children.

#### *Potential output of children*

24. On the production side of fertility determination, the key analytical concept is the potential output of children, the number of surviving children a household would have if fertility were not deliberately limited. This depends, in turn, upon natural fertility and the probability of a baby surviving to adulthood. Given natural fertility, an increase in infant survival prospects would increase the potential output of descendant children. Similarly, given survival prospects, the potential output of children would vary directly with natural fertility.

25. The motivating force behind natural fertility is not the demand for children, but sexual desire, which influences fertility through frequency of intercourse. Coital frequency is also affected by involuntary abstinence due to such factors as impotence or illness.

Moreover, in addition to frequency of intercourse, natural fertility depends upon fecundity or infecundity, as affected by involuntary causes, and upon foetal mortality from involuntary causes. (Sociologists will notice that the terminology here is that of the well-known Davis and Blake article.<sup>20</sup>)

26. Natural fertility depends in part upon physiological or biological factors and in part upon cultural practices. Included under the biological head would be factors that influence natural fertility through such mechanisms as genetic influences on fecundity or the effect of disease and malnutrition on coital frequency and the ability to carry a foetus to full term. Under the cultural head would be various social customs or events that inadvertently affect coital frequency, fecundity, or foetal mortality, such as the belief that sexual intercourse should be avoided while a mother is nursing (an "intercourse taboo") or physical separation of partners due to such things as civil strife or seasonal migration for employment purposes. Two societies identical in biological and physiological characteristics might differ in natural fertility because, for example, an intercourse taboo led to a higher prevalence of involuntary abstinence in one society than in the other. As has been mentioned, natural fertility in a given society is likely to be below the reproductive potential of the population because of both biological constraints and cultural conditions that inadvertently reduce family size.

#### *Motivation for fertility regulation*

27. The potential output of and demand for children jointly determine the motivation for fertility regulation. If the potential output falls short of demand, there is no desire to limit fertility; on the contrary, an "excess demand" situation of this type would result in a demand for ways to enhance fertility and for the adoption of children, although these possibilities are usually quantitatively unimportant. Households might have knowledge of the means of regulating fertility, but there would be no incentive to use them. In this situation, parents would be expected to have as many children as possible; that is, the number of children parents actually have would correspond to their potential output. Variations in the number of children parents have would arise from variations in the determinants of potential output, namely, natural fertility and the probability of an infant surviving to adulthood.

28. On the other hand, if the potential output exceeds demand, an "excess supply" situation, parents would be faced with the prospect of having unwanted children and would be motivated to regulate their fertility. In an excess supply situation, therefore, there is a demand for ways of limiting fertility. Whether fertility control will actually be used, however, depends upon how the costs of fertility regulation compare with the motivation to limit fertility.

<sup>19</sup> M. L. Wachter, "Government policy towards the fertility of the poor", *Fels Discussion Paper No. 19* (Philadelphia. The University of Pennsylvania-Philadelphia, The Fels Center of Government, 1972).

<sup>20</sup> K. Davis and J. Blake, "Social structure and fertility", *Economic Development and Cultural Change*, vol. IV, No. 3 (April 1956), pp. 211-235.

### *The costs of fertility regulation*

29. While motivation is a necessary condition for fertility regulation, it is not a sufficient condition. Fertility regulation imposes costs on the household of two types. There are psychic costs—the displeasure associated with the idea or practice of fertility control—and market costs—the time and money necessary to learn about and use specific techniques. These costs, in turn, depend upon the state of attitudes in society towards the general notion of fertility control and towards specific techniques, and the degree of access to fertility control, in terms of both the availability of information and the range of specific techniques and their prices. Typically, a family-planning programme lowers market costs by increasing information and providing services free or below cost, and also lowers subjective costs by lending legitimacy to the notion of practising birth control.

30. Whether in a given excess supply situation fertility control will actually be used depends upon how the costs of fertility regulation compare with the motivation to limit fertility. Given the strength of the motivation, the lower the costs of fertility regulation, that is, the more nearly conditions approach those of the “perfect contraceptive society”, where psychic and market costs would be zero,<sup>21</sup> the greater would be the adoption of fertility regulation and the more nearly would the number of children parents have correspond to the number they desire. Conversely, the higher the costs of fertility control, the more nearly would actual conditions approach the potential output of children, the lower would be the deliberate control of fertility, and the greater would be the number of unwanted children.

### *Summary*

31. In the present analysis, the determinants of fertility are seen as working through one or more of the following: the demand for children if fertility regulation were costless, the potential output of children if no conscious effort were made to control fertility and the costs of fertility regulation. The immediate determinants of the demand for children are income, the price of children in relation to goods and subjective preferences for children compared with goods. The potential output of children depends upon natural fertility and the survival prospects of a baby to adulthood. The costs of fertility regulation include subjective costs (“attitudes”) as well as the time and money necessary to learn about and use specific techniques (“access”).

32. The role of these factors in determining actual fertility differs depending upon the comparative state of the potential output of and the demand for children. If the situation is one of excess demand, or even if it is

one of excess supply, but the motivation for fertility control falls short of the costs, then the number of children parents have corresponds to their potential output, and the determinants of potential output govern variations in actual output. If, however, the situation is an excess supply one in which the motivation to regulate fertility exceeds the costs, then deliberate limitation of fertility occurs and the number of children parents have falls below potential output. Yet, as long as fertility regulation is not entirely costless, some parents still have unwanted children. The situation is thus one in which the actual number of children parents have falls short of potential output, the difference reflecting the extent of conscious fertility control, but the actual number exceeds the desired number, the excess consisting of the number of unwanted children.

### LINKS BETWEEN MODERNIZATION AND THE DETERMINANTS OF REPRODUCTIVE BEHAVIOUR

33. Among the complex of changes embraced by modernization, several seem especially important in bringing about the shift to modern conditions of child-bearing. Historically, these have been:

- (a) Innovations in public health and medical care;
- (b) Innovations in formal schooling and mass media;
- (c) Urbanization;
- (d) The introduction of new goods;
- (e) *Per capita* income growth.

More recently, in a few countries another aspect of modernization—family planning programmes—has perhaps also played a noticeable role in influencing reproductive behaviour.

34. The table given below presents a summary view, based on the framework just sketched, of the channels through which reproductive behaviour is influenced by these various aspects of modernization. The aspects of modernization are listed on the left-hand side, and the principal factors immediately relevant to fertility determination, at the top, as column headings. An entry in a cell indicates that the specified item on the left influences the fertility determinants at the top in the direction shown. For example, the negative sign in column 1 of row 4a indicates that, other things being equal, the introduction of new consumer goods during modernization tends to reduce the strength of preferences for children in relation to goods, and, thus, the desired number of children. In drawing up the table, an attempt has been made to identify, on the basis of the literature, what appear to be the most important links between modernization and reproductive behaviour, rather than all hypothetically possible connexions. Thus, the absence of an entry in a cell does not necessarily mean that no relation whatever exists, but that typically it is probably not very important. The reasoning underlying the specific cell entries follows.

DIRECTION OF EFFECT OF VARIOUS ASPECTS OF MODERNIZATION ON INDICATED DETERMINANTS OF NUMBER OF SURVIVING CHILDREN PER MARRIED WOMAN

Aspect of modernization	Factors through which family size is influenced						
	Demand for children			Potential output		Costs of fertility regulation	
	Tastes (1)	Income (2)	Prices (3)	Natural fertility (4)	Survival prospects (5)	Subjective (6)	Market (7)
1. Better public health and medical care <sup>a</sup>				+	+		
2. Growth in formal education and mass media <sup>a</sup>	-		-	+	+	-	-
3. Urbanization <sup>a</sup>	-		-		-	-	-
4. New goods							
a. Consumer goods	-						
b. Fertility control						-	-
5. Per capita income growth	-	+		+	+		

<sup>a</sup> To the extent this item also increases *per capita* income, additional effects as shown in line 5 would occur.

*Public health and medical care*

35. Improved public health and medical care in the course of modernization impinges on the reproductive situation of the family by tending to increase the potential output of children in two ways. First, it is likely to increase the natural fertility of women, because, for example, healthier women are more likely to carry a foetus to full term.<sup>22</sup> Secondly, even if natural fertility were unchanged, infants are more likely to survive to adulthood, and the potential output of children would be correspondingly increased. These relationships are indicated in the table by the positive signs in columns 4 and 5 of row 1.

36. Furthermore, better public health and medical care may raise *per capita* income, because a healthier, more energetic population is likely to be more productive.<sup>23</sup> Increased *per capita* income, in turn, influences a number of fertility determinants over and beyond the effects of better health just mentioned. However, to simplify the table, only the effects directly attributable to public health and medical care improvements are shown, not those that might indirectly be induced through the effect of better health on *per capita* income. As indicated in the foot-note to the table, a full accounting for the effects of improved public health and medical care would also take account of the indirect consequences as a result of *per capita* income growth, shown in line 5. The same treatment has been followed in the table with regard to the next two aspects of modernization, improved education and urbanization,

each of which may raise *per capita* income as well as influencing reproductive behaviour directly. The effects shown in the row for each of these factors exclude any indirect consequences they may have as a result of increased *per capita* income. Correspondingly, in principle, the full range of effects of each of these factors comprises not only that shown on its respective line, but that shown in line 5 for *per capita* income growth.

*Education and mass media*

37. Turning to the growth of formal education and the associated expansion in mass media, even disregarding any effects resulting from *per capita* income growth, one finds this to be one of the most pervasive factors influencing completed family size. As shown in the table, it operates on all three of the principal fertility determinants—demand, potential output and the costs of fertility regulation. The impact on potential output may be touched on first, since the reasoning is much like that in regard to the effect of public health and medical care improvements. Formal education and expanded mass media improve health conditions by diffusing improved knowledge with regard to personal hygiene, food care, environmental dangers and so on. They may also break down traditional beliefs and customs and thus undermine cultural practices, such as an intercourse taboo, which have had the latent function of limiting reproduction. In these ways they tend to enhance the potential output of children by raising natural fertility and/or increasing the survival prospects of babies; hence, the positive signs in columns 4 and 5 of row 2.

38. Education and the mass media tend, too, to lower the costs of fertility regulation, as shown by the negative signs in columns 6 and 7. They may provide information not formerly available on various means

<sup>22</sup> J. Bourgeois-Pichat, "Relation between foetal-infant mortality and fertility", *World Population Conference, 1965*, vol. II, *Fertility, Family Planning, Mortality* (United Nations publication, Sales No. 66.XIII.6), pp. 68-72.

<sup>23</sup> W. Malenbaum, "Health and productivity in poor areas", in H. E. Klarman, ed., *Empirical Studies in Health Economics* (Baltimore, Maryland, Johns Hopkins Press, 1970), pp. 31-54.

of fertility control, reducing the expense in time and money previously required. They may also alter cultural norms adverse to the use of fertility control, and thus lower the subjective costs of fertility regulation, by challenging traditional beliefs and encouraging a problem-solving approach to life.

39. Lastly, formal education and the expansion of the mass media tend to reduce the demand for children by shifting tastes in a manner unfavourable to children and decreasing the price of goods in relation to children (row 2, columns 1 and 3). With regard to the relative price of children, if better education improves the income-earning possibilities of women, then the alternative cost of the mother's time required in child-rearing is increased. While some offset to this may be available, for example, through the help of domestics or other family members, there is probably some net positive effect on the cost of children and thus a tendency towards a reduction in desired family size. In addition, compulsory education may increase the relative cost of children by reducing the possible contribution of child labour to family income.

40. Tastes for children, more specifically the intensity of the desire for children in relation to goods, are affected negatively by education because children, and the life-style associated with them, are essentially an "old" good, while education and the mass media present images of new life-styles competitive with children. Deborah S. Freedman has found that the more people have been exposed to modern influences, as indicated by their education and exposure to mass media, the more likely they are to want modern goods and services.<sup>24</sup> Another possibility, receiving much emphasis today, is a "liberated" life-style for women, involving greater market work and less family activity. Furthermore, education and the mass media may lead to higher standards with regard to child-care and rearing, creating greater emphasis on the "quality" of children at the expense of numbers. (Note that this is a taste, not a "cost" effect, since it works through a change in subjective attitudes and not a market phenomenon.) In these ways, education and the mass media increase the subjective attractiveness of expenditures competitive with having more children, and thus tend to lower desired family size.

41. These developments are part of a more general shift in attitudes that takes place during modernization. This shift is brought about not only by education and the mass media, but by the population's increasing urbanization and participation in other modern institutions like the factory and agricultural co-operative. A valuable summary description of this development is provided by Inkeles:

"We believe our evidence . . . shows unmistakably that there is a set of personal qualities which reliably

<sup>24</sup> D. S. Freedman, "The role of modern durables in economic development", *Economic Development and Cultural Change*, vol. XIX, No. 1 (October 1970), pp. 25-48.

cohere as a syndrome and which identify a type of man who may validly be described as fitting a reasonable theoretical conception of modern man. Central to this syndrome are: (1) openness to new experience, both with people and with new ways of doing things such as attempting to control births; (2) the assertion of increasing independence from the authority of traditional figures like parents and priests and a shift of allegiance to leaders of government, public affairs, trade unions, cooperatives, and the like; (3) belief in the efficacy of science and medicine, and a general abandonment of passivity and fatalism in the face of life's difficulties; and (4) ambition for oneself and one's children to achieve high occupational and educational goals. Men who manifest these characteristics (5) like people to be on time and show an interest in carefully planning their affairs in advance. It is also part of this syndrome to (6) show strong interest and take an active part in civic and community affairs and local politics; and (7) to strive energetically to keep up with the news, and within this effort to prefer news of national and international import to items dealing with sports, religion, or purely local affairs."<sup>25</sup>

42. Among others, Ronald Freedman has emphasized the fertility implications of these attitudinal changes, citing involvement with "the ideas and institutions of a larger modern culture" as a basic factor in the transition to lower fertility.<sup>26</sup>

#### Urbanization

43. The process of economic modernization requires a redistribution of population from rural to urban areas, and this is largely accomplished by a vast increase in rural-urban migration. Sociologists have traditionally stressed the implications for reproductive behaviour of this aspect of the modernization process, and in a recent paper, Kuznets too has assigned an important role to this factor.<sup>27</sup> Urbanization, like education, reduces the demand for children by reducing tastes and lowering the price of goods in relation to children (row 3, columns 1 and 3). (The possible effects resulting from *per capita* income change continue to be set aside.) The effect deriving from tastes has been touched on immediately above. With regard to costs, the available evidence indicates that the relative price of children of

Ryder, "The character of modern fertility", *The Annals of the American Academy of Political and Social Science*, vol. CCCLXIX (January 1967), pp. 26-36.

<sup>27</sup> Simon Kuznets, "Population trends and modern economic growth—notes towards a historical perspective", *Population Debate*, vol. I, part four; D. Kirk, *Europe's Population in the Interwar Years* (League of Nations publication, Sales No. II Economic and Financial 1946.II.A.8); F. Lorimer, *Culture and Human Fertility* (Paris, United Nations Educational, Scientific and Cultural Organization, 1954).

a given "quality" is usually higher in urban areas than in rural.<sup>28</sup> A variety of factors are responsible for this. The price of food is higher in urban areas than in rural. Also, farm children take less time away from a mother's paid work and contribute more time towards family work than do urban children. In both cases, this would raise the relative cost of children in urban areas compared with rural. Thus, the effect of urbanization of the population is increasingly to place the population in an environment where goods become relatively less expensive than children, and, other things being equal, correspondingly more attractive.

44. In regard to the potential output of children, urbanization is probably a negative influence, tending in itself to lower the survival prospects of children (row 3, column 5). The reasoning here is that concentration in densely populated areas increases exposure to disease and tends, other things being unchanged, to raise mortality. The result would be a lower number of surviving children from a given number of births. This effect may be less applicable, however, under the more modern public health and medical conditions in urban areas in many of today's less developed nations than it was in the historical experience of the developed countries.

45. Lastly, urbanization tends to reduce both the subjective and market costs of fertility regulation, in ways much like those of formal education and expanded mass media (row 3, columns 6 and 7). In higher density urban situations, access to fertility control knowledge is likely to be greater and market costs consequently reduced. Subjective costs, too, are likely to be less, because of the role of the urban environment in breaking down traditional attitudes, among them the reluctance to try new ways of doing things.

#### *New goods*

46. Another facet of economic modernization is the continuing introduction of new goods.<sup>29</sup> The association between increased consumption of modern goods and reduced fertility has been noted in recent studies. In terms of the present framework, the introduction of new goods tends to lower the demand for children by shifting tastes in an adverse manner, as shown by the negative sign in row 4a, column 1. The enjoyment of new goods tends to require life-styles other than those centred on children, since new goods are typically substitutes for, rather than complementary with, children. Thus, holding other factors constant, the relative strength of household desires for goods unrelated to children is increased and desired family size decreased. At any given level of income, households would tend to shift expenditure towards new purposes and away

from old goods, including in the latter, having and raising children.

47. Among the new goods associated with modernization are some specifically related to fertility control. Historical examples are the modern condom and improved methods of induced abortion; more recently, the oral contraceptive pill and the intra-uterine device (IUD). Such developments typically reduce market costs of fertility regulation by providing cheaper methods. They may also lower the subjective costs of fertility regulation by providing less objectionable options to the household. For example, an advantage claimed for both the pill and IUD compared with most other methods is that they separate the contraceptive act from that of intercourse. Allowance for the effects of new methods of fertility control is made in the table by the negative signs in columns 6 and 7 of row 4b.

#### *Per capita income growth*

48. Lastly, attention is focused on the effects of *per capita* income growth, whether due to the aspects of modernization in lines 1-3 of the table, or to other factors, such as the adoption of modern techniques of production. In the economic analyses of fertility, the effect of *per capita* income change typically stressed is a positive effect. On the assumption that children are normal goods, one expects, other things being equal, that higher income would encourage households to want more children, just as higher income encourages greater consumption of goods in general. This influence is shown by the positive sign entered in row 5, column 2.

49. However, there is another and counteracting effect of *per capita* income growth on the demand for children, operating by means of tastes, as shown by the negative sign in row 5, column 1.<sup>30</sup> Because of the substantial upward trend in living levels during economic development, each generation typically comes from a more prosperous background than the preceding generation. Because of this, the views of each successive generation as to the material requisites of the "good life" tend to be progressively higher. Goods which to one generation may have been luxuries become necessities to the next—the motor-car is a case in point. This "intergeneration taste effect", as it might be called, tends to raise the minimum living level which parents feel is necessary before they can "afford" to have children.

50. Thus, while *per capita* income growth increases the resources available to households, it also affects the consumption aspirations which persons acquire in their economic socialization. Moreover, since the

<sup>28</sup> P. Lindert, "The relative cost of American children", *Graduate Program in Economic History* (Madison, The University of Wisconsin-Madison, 1973), paper EH 73-18.

Easterlin, "Towards a socioeconomic theory of fertility . . ."; H. Leibenstein, "The economic theory of fertility decline", *Harvard Institute of Economic Research Discussion Paper No. 272* (Cambridge, Massachusetts, Harvard University, 1973).

escalation in consumption aspirations is itself a reflection of actual income growth, this means that the adverse taste effect of such growth tends to be strong enough, on the average, to wash out the positive income effect. (Over shorter periods, however, the two effects of income growth may get out of phase, producing fluctuations in fertility.<sup>31</sup>) The taste effect of income growth operates within generations as well as between them.

51. The foregoing effects of *per capita* income growth operate through the demand for children. As has been stated, *per capita* income growth may also affect potential output of children, especially in the early stages of modernization. In terms of personal consumption experience of the population, *per capita* income growth typically comprises, among other things,

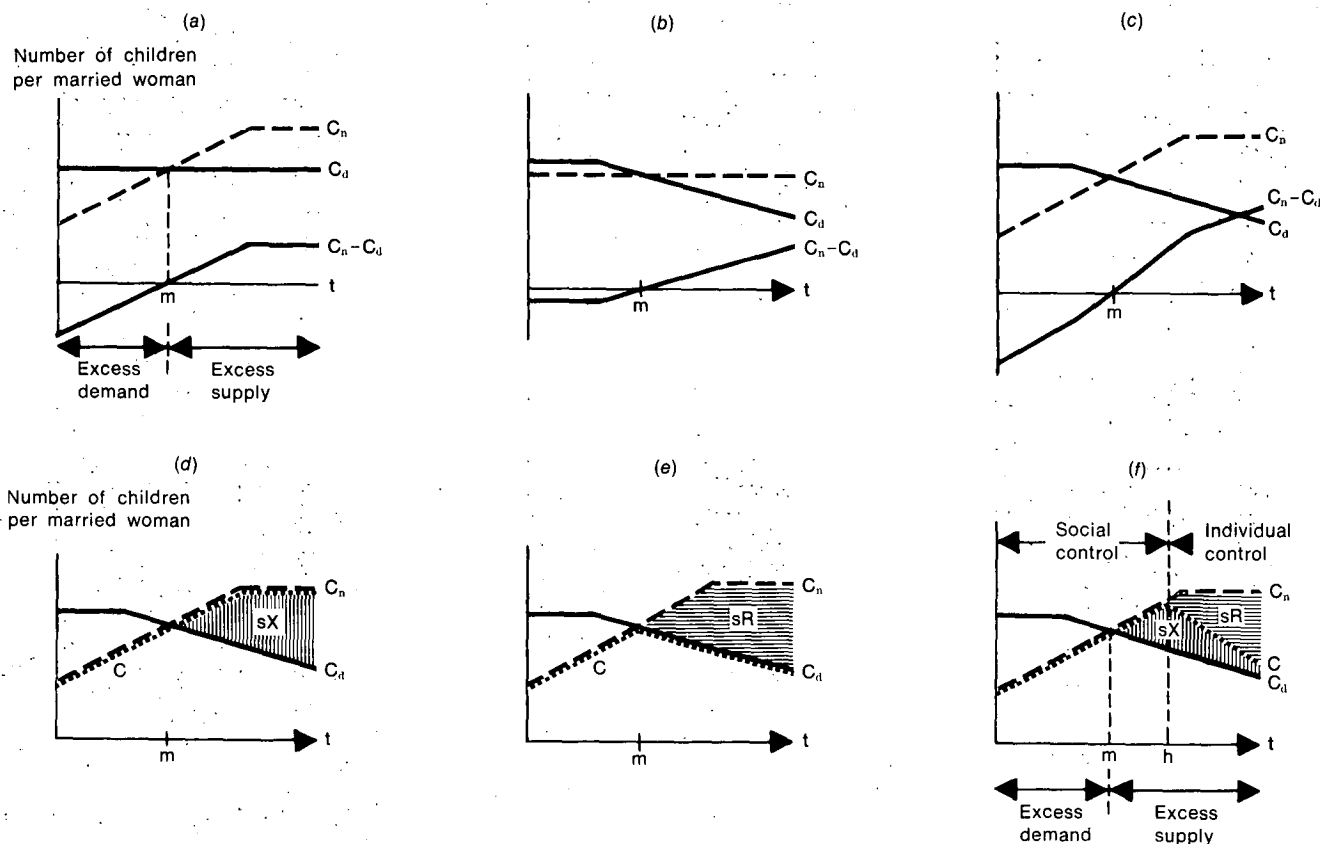

<sup>31</sup> R. A. Easterlin, *Population, Labor Force, and Long Swings in Economic Growth: The American Experience* (New York, Columbia University Press, 1968).

substantial advances in food, clothing and shelter. The consequent improvement in resistance to disease and reduction in exposure to disease are likely to raise the fecundity of women and increase prospects of infants surviving to adulthood. These influences are shown in the table by the positive signs entered in columns 4 and 5 of row 5.

#### A MODEL OF THE EFFECTS OF MODERNIZATION ON FAMILY REPRODUCTIVE BEHAVIOUR

52. The preceding section suggests a number of specific ways that modernization affects the demand for children, potential output of children, and costs of fertility control. These influences are brought together in figure II to develop a schematic model of the impact of modernization on family reproductive behaviour. In figure II, the solid line  $C_d$  curve refers to the desired number of surviving children of the representative

Figure II. Hypothetical trends in fertility variables associated with economic and social modernization

#### Legend

The following definitions all refer to the total number over the reproductive career of the "representative" household:

- $C_n$  is the number of surviving children parents would have in an unregulated fertility régime
- $C_d$  is the desired number of surviving children in a perfect contraceptive society
- .....  $C$  is the actual number of surviving children
- |||||  $sX$  is unwanted children, the excess of the actual number of children over the desired number
- ====  $sR$  is the degree of voluntary fertility regulation, measured in terms of children averted

household and the broken line  $C_n$  curve, to the potential output. In all of the diagrams, the progress of modernization is assumed to be correlated with time, and corresponds to a rightward movement along the  $x$ -axis. Note that in contrast to figure I, the magnitudes plotted here refer to surviving children, not to births.

#### *Effects on the motivation to regulate fertility*

53. Diagrams II(a) through II(c) sketch alternative ways in which the motivation to deliberately limit fertility tends to grow as a result of modernization. In II(a), the influences on the potential output of children, summarized in columns 4 and 5 of the table, are shown by the upward movement of the  $C_n$  curve, which eventually levels off as modern health and living levels are established. It is assumed that the several factors in the table operating to increase potential output outweigh, in the long run, the one tending to decrease potential output. Even with desired family size remaining constant ( $C_d$  horizontal), the net balance of potential output *versus* desired size shifts in an excess supply direction, as shown by the  $C_n - C_d$  curve at the bottom of the diagram. To the right of point  $m$ , the typical household is in the situation of potentially producing more children than it wants. Hence, it has an incentive to limit fertility in order to avoid unwanted children. This provides an illustration of how public health programmes, which at first raise the population growth rate through their impact on survival prospects, tend eventually to a motivation for lower fertility and, thus, reduced population growth.

54. Diagram II(b) illustrates how the demand influences, in columns 1-3 of the table, tend to bring about excess supply conditions, even if potential output remains unchanged. The net balance of the demand influences in the table is taken to be negative, despite the positive sign for the income effect, since as was noted, the latter tends to be balanced out, on the average, by the intergenerational taste effect. In the diagram, the  $C_d$  curve is at first horizontal, a condition which would occur if the new demand influences began to make themselves felt only some time after the modernization process had begun.

55. Diagram II(c) illustrates the most likely circumstance, that in which influences on both potential output and desired family size are acting in a mutually reinforcing way to bring about a motivation to regulate fertility as modernization progresses. Because of this the  $C_n - C_d$  curve, which shows the net balance of potential output and demand influences, shows a more pronounced upward movement. In the subsequent diagrams in the figure, the demand and output conditions shown in diagram II(c) are assumed to apply, and, for simplicity the  $C_n - C_d$  curve depicting the net balance between the two is omitted.

56. The pre-modern situation, shown in all diagrams of figure II, is one of excess demand; that is, parents are unable to produce as many children as they would like. There is some evidence that such conditions may

prevail in some less developed areas.<sup>32</sup> However, the present analysis could readily be modified to take account of other pre-modern circumstances. Thus, one might assume that the  $C_d$  and  $C_n$  curves are superimposed on the pre-modern section of the diagram, that is, that parents at first have just as many children as they would like. Or one might assume that  $C_n$  exceeds  $C_d$  by a small margin, but that pronounced fluctuations in fertility give rise to so much uncertainty among parents about realizing their family size desires that they act as though they are in an excess demand situation, even though the actual situation over the long run is one of excess supply. Another variant would be a situation in which excess supply conditions and deliberate fertility control exist among a small segment of the population, but the bulk of the population is in an excess demand condition. In all cases, the only critical point is that modernization results in substantially increased prospects of unwanted children among the mass of the population.

#### *Costs of fertility regulation*

57. As previously stated, in an excess supply situation, the number of children parents actually have depends upon how the motivation to regulate fertility balances against the costs of fertility control. In seeking to determine the likely course of the actual number of children during modernization, it is necessary to consider these costs. Three alternative situations are considered in which fertility control costs remain fixed at different assumed initial levels, and then the effect of the changes in costs are described.

58. Diagrams II(d) and II(e) illustrate the two extremes with regard to costs of fertility regulation. Diagram II(d) represents the situation in which fertility control costs are prohibitive—one might imagine a situation, for example, in which no one knows how to control fertility. Diagram II(e) represents the situation in which there are no subjective or market costs of fertility control, the "perfect contraceptive society". As shown in diagrams II(d) through II(f) the trend in motivation to control fertility is assumed to be that shown by the  $C_n - C_d$  curve in diagram II(c). In both diagrams II(d) and II(e), to the left of point  $m$  parents are not able to have as many children as they would like to have. As a result, in this range the actual number of children they have, shown by the dotted  $C$  line, is equal to the maximum amount they can produce, as indicated by the  $C_n$  curve, and rises as potential output increases. As one moves to the right of point  $m$  in both diagrams, a problem of unwanted children emerges, giving rise to the motivation to regulate fertility. In diagram II(d), where the costs of fertility regulation are prohibitive, the curve for the actual number of children,  $C$ , continues to follow the potential output curve,  $C_n$ , and unwanted children increase. The number of unwanted children is shown by the vertical distance between  $C$

<sup>32</sup> R. B. Tabbarah, *loc. cit.*

and  $C_d$ , marked  $sX$ . On the other hand, in diagram II(e), the situation of the "perfect contraceptive society" where subjective and market costs of fertility regulation are zero, as soon as the motivation to regulate fertility occurs, parents immediately do so. The actual number of children,  $C$ , falls short of the maximum possible,  $C_n$ , and follows the  $C_d$  curve, turning downward in the case shown. The extent of fertility regulation, measured in children averted, is shown by the vertical  $sR$  distance between  $C_n$  and  $C$ . ( $s$  is the survival rate from infancy to adulthood and is used here to convert the excess fertility and births averted magnitudes of figure I into numbers of children.)

59. In any real world situation, fertility control costs would be neither zero nor prohibitive. The likely course of the actual number of children for a given level of fertility costs, intermediate between those represented in diagrams II(d) and II(e), is shown in diagram II(f). At first, as the potential output curve,  $C_n$ , edges above the desired number of children,  $C_d$ , to the right of point  $m$ , the motivation to regulate fertility is not great enough to offset the costs, and the actual number of children continues to be governed by the  $C_n$  curve, with unwanted children increasing as shown by  $sX$ . As the rightward movement continues, however, a point is reached at which the loss in welfare due to unwanted children begins to exceed that associated with the costs of fertility regulation. In effect, a "threshold" of deliberate fertility control, marked  $h$  in the diagram, is reached.<sup>33</sup> Fertility regulation is introduced and the  $C$  curve turns downward in the direction of  $C_d$  curve, with fertility regulation practised to the extent shown by the vertical distance  $sR$ . As long as costs of fertility regulation are positive, however, there will continue to be some unwanted children, indicated by  $sX$ . This is the price parents pay for their reluctance to bear the psychic and market costs of fertility regulation.

60. A reduction in fertility control costs during modernization, due to the factors shown in columns 6 and 7 of the table, would, other things being equal, shift the threshold point  $h$  to the left, increasing fertility regulation and reducing the number of unwanted children at any given time  $t$ . A steady down-trend in fertility control costs would cause the fertility decline to occur earlier and be steeper in magnitude than would otherwise be the case. In a perfect contraceptive society with zero fertility control costs, the threshold point  $h$  would be identical with point  $m$ , that is, prevention of births would occur immediately on the emergence of excess supply conditions, and the  $C$  curve beyond point  $m$  would be identical with the  $C_d$  curve, as shown in diagram II(e).

61. Note that the threshold point,  $h$ , depends not upon any given values of  $C_n$  and  $C_d$ , but upon the

difference between the two. As is clear from diagrams II(a) through II(c), quite different combinations of  $C_n$  and  $C_d$  can yield the same degree of motivation. The threshold point will also vary with the costs of fertility control. There is, thus, no *a priori* reason to expect the threshold of fertility control always to occur at the same stage of modernization, for quite different threshold points may arise from different combinations of  $C_n$ , and  $C_d$ , and the costs of fertility control.

#### The general pattern

62. Figure I identified the principal trends in family reproductive behaviour associated with the process of modernization, namely, declines in observed and desired fertility, and an increase in conscious fertility control by the individual household. The table and figure II attempt to clarify the channels through which modernization operates to produce these trends. A summary statement of the process is, perhaps, appropriate at this point.

63. First, there is a pre-modern situation in which the representative household is in a situation where there is no motivation to limit fertility, since parents are uncertain about being able to have as many children as they would like to have. (As stated, this "typical" situation is consistent with the deliberate regulation of fertility among a limited segment of the population.) Until the threshold of fertility regulation is reached, the number of children parents have is governed by the factors determining  $C_n$ , specifically natural fertility and child survival prospects. Indeed, since modernization typically exerts a positive impact on each of these factors, there may be a tendency for actual family size to increase during the early phase of modernization. Some evidence of such increases has been found.<sup>34</sup> In this early stage of modernization, while desired family size and the costs of fertility regulation may be changing in a negative direction, these factors are unlikely to influence actual family size, because the typical household has not yet felt a motivation for fertility control sufficient to overcome the costs. Here is an example of a situation in which the establishment of a family planning programme would meet with little or no response, because there is insufficient motivation among

<sup>33</sup> D. Kirk, "A new demographic transition?", in National Academy of Sciences, *Rapid Population Growth* (Baltimore, Maryland, Johns Hopkins Press, 1971), vol. II, pp. 123-147; *Conditions and Trends of Fertility in the World* (United Nations publication, Sales No. 64.XIII.2):

Shorter, "Women's liberation, birth control and fertility in European history", paper presented at the annual meeting of the American Historical Association, December 1971.

the public to regulate fertility.<sup>35</sup> Nevertheless, decreases in desired family size and the costs of fertility control would move the threshold of fertility regulation closer.

64. Eventually, as modernization progresses, the typical family moves across the threshold of fertility regulation, and fertility turns downward as deliberate control of fertility expands. In part, as just stated, this may be due to a gradual reduction in the desired family size and in the costs of fertility regulation. In part, it is caused by the increase in potential output itself, which increases motivation for fertility control by raising progressively the family's prospective number of unwanted children. In this sense, developments raising the potential output of children are partially self-correcting, since, as they continue, they tend eventually to induce the adoption of fertility regulation and thereby a reduction in family size. Moreover, with regard to the effect of an increase in child survival prospects, a downward influence on fertility is exerted over and above that working through completed family size. For households to achieve a given number of surviving children, the necessary number of births would be lower, the better the prospect of infant and child survival. Because of this, one would expect the downward movement in fertility, due to increased child survival prospects, to be greater than that in completed family size, once fertility regulation is adopted.

65. The present scheme helps bring out the way in which different economic and social programmes influence fertility. Although in the short run, health programmes may raise fertility through their effect on natural fertility, eventually they induce a decline in fertility, as households become aware of an excess fertility problem and as the motivation to regulate fertility emerges. As Tabbarah has pointed out, without such motivation, family planning programmes are fruitless.<sup>36</sup> However, once such motivation exists, family planning services can hasten the decline in fertility through their impact on the costs of fertility regulation. Neither health nor family planning programmes, however, would ordinarily change  $C_d$ , desired family size. The latter, as Kingsley Davis has emphasized, calls for changes in the economic and social environment.<sup>37</sup> Examples would be policies in the areas of economic development and education, which lead to the emergence of new living-level aspirations and new role models among the public, and which, thereby, reduce family size desires by raising the value of life-styles competitive with having children. The question of the appropriate policies for reducing fertility, therefore, is not an either-or matter, but one of the optimal policy mix.

66. Lastly, it should be mentioned that diagram II(f) helps distinguish between the two modes of fertility regulation described in the earlier quotation of Bourgeois-Pichat. The threshold point  $h$  in diagram II(f) may be thought of as the dividing line. To the left of point  $h$ , fertility is "regulated" by a variety of social and biological mechanisms working through natural fertility. Fertility is not yet viewed by the household as involving a potential problem of unwanted children, and is, in effect, outside the standard household decision-making calculus. The modernization process, which shifts the typical household to a position to the right of point  $h$ , causing a fundamental change in the circumstances of family reproduction, moving the household from a situation where child-bearing is a matter "taken for granted" to one posing difficult problems of individual choice concerning the limitation of family size. To the left of point  $h$ , although there is a demand for children, the usual demand mechanisms emphasized in the economic theory of fertility do not influence fertility, though fertility may be affected by economic variables raising or lowering potential output. The explanation of fertility in such a situation calls for inquiry along these lines by sociologists and other students of natural fertility. To the right of point  $h$ , the household decision-making approach of economics comes into its own. Even here, of course, sociology still has an important part to play, particularly in the investigation of taste formation. To dramatize this contrast, the sections to the left and right of point  $h$  in diagram II(f) have been labelled, respectively, "social control" and "individual control", following Bourgeois-Pichat's terminology. Such sweeping distinctions are never fully satisfactory. Social sanctions are operative in both pre-modern and modern circumstances, while the idea that there is no individual choice whatsoever in a pre-modern society is too strong. Moreover, no society shifts *en masse* at a single point of time from the "social" to "individual" control situations. The real world process would inevitably be characterized by timing differences between various groups in the population.

67. The proposition that there is a change in the basic nature of fertility regulation should not be confused with the view expressed by some writers that rational attitudes towards human reproduction emerge only with modernization. In the present analysis, pre-modern reproductive behaviour is rational in the sense that the means are appropriate to the end. Given a conception of the problem as one of having enough surviving children, maximization of output within the existing set of biological constraints and established social practices makes sense. The process of modernization alters not the rationality of the individual, but the nature of the problem, from one of having too few children to one of having too many. Perception by individual households of this change in the nature of the problem and the devising of means to cope with it would hardly be expected to be instantaneous—hence, the persistence of high fertility in circumstances where

it is no longer needed. But this lag in the adjustment of fertility is a temporary one and is understandable, given the turn-around that has taken place in the nature of the problem, and is no evidence of irrationality.

68. It is possible that the emergence of a pressure for fertility limitation is one of the first forms in which modernization impinges directly on the mass of the population. The appearance of a problem that had not previously existed, that of limiting family size, and, thereby, of a need for decision-making of an entirely new sort, gives rise to a pressure for attitudinal changes in a fundamental and immensely personal area of human experience. From this point of view, the "population problem" may have positive consequences, by contributing to modernized attitudes that may more generally favour economic and social development. The presence of appropriate family planning services may facilitate this shift and ease the psychological pressures on individuals by increasing the likelihood of resort to "modern" techniques of fertility regulation, rather than to cruder traditional methods.

#### *The variability of experience*

69. The foregoing sketch attempts to bring together the variety of factors operating to induce changes in family reproductive behaviour during modernization. There is, of course, no necessity for these factors to operate simultaneously or with equal force in all real world situations. While the basic economic and social changes listed in the table have invariably occurred in all countries which have modernized, their relative timing has by no means been uniform. Moreover, the economic changes are usually more protracted, whereas social changes in public health and compulsory elementary education may be more concentrated temporarily. One would expect, therefore, considerable variability in the patterns of change in reproductive behaviour actually observed.

70. By making different assumptions concerning changes in the basic fertility determinants, it is possible to generate with the present framework a variety of patterns of change, as may be illustrated with reference to the shift from high to low fertility. The typical demographic transition pattern—a shift from high to low mortality preceding a corresponding movement in fertility<sup>38</sup>—may be most simply generated, if, with other fertility determinants given, one assumes mortality is sharply reduced in a situation beginning with high mortality and fertility. The accompanying increase in child survival prospects, and perhaps also in natural fertility of mothers due to better health, would raise  $C_n$ , shifting the typical household into an excess supply situation of the type shown to the right of point  $m$  in diagram II(a). As the prospect of unwanted children continued to grow, the typical household would, in time, reach and

cross the fertility control threshold  $h$ , and fertility rates would begin to move downward, thus following with a lag the decline in mortality.

71. Coale has remarked on situations in which the fertility decline accompanied or preceded the mortality decline.<sup>39</sup> Such a pattern could arise from changes in the economic and social structure, which give rise to unwanted children by shifting  $C_d$  below a given  $C_n$ , in the manner shown to the right of point  $m$  in diagram II(b). In this case, a fertility decline might be induced in the absence of or contemporaneously with a mortality decline.

72. As these examples show, there is no necessity for any one aspect of modernization, such as mortality decline, to exhibit an invariant timing pattern in relation to actual fertility. Many scholars have emphasized that the fertility movements actually observed as different countries modernize are highly variable.<sup>40</sup> The present model points to a number of reasons for this. The initial pre-modern conditions, such as levels of desired family size, potential output of children and fertility control costs, may differ among countries. So too may the historical trend in a particular aspect of modernization, such as the rapidity with which the movement towards universal elementary education takes place. Again, the various factors may come together in different combinations; for example, in one case economic development may substantially lead social modernization, and in another, the opposite may be true.

73. One may ask whether the same framework can encompass both the historical experience of the developed countries and the current experience of less developed countries; and whether it is likely that today's less developed countries will experience the same pressures for fertility reduction that emerged in the developed countries. The answer to this is yes, because the same aspects of modernization, listed in the table, that gave rise to these pressures in the developed countries are occurring in today's less developed countries. Advances in public health and education are occurring at an earlier time in relation to economic modernization than was true of the developed countries. Moreover, new influences are at work that were previously absent, for example, government family planning programmes,

mass media in the form of television and new modes of fertility regulation such as the IUD.<sup>41</sup>

74. Substantial differences in historical patterns of fertility change may arise, not only from variations in the secular factors at work, but from differential fluctuations as well. In pre-modern conditions substantial variations in fertility occur in connexion with movements in natural fertility due to epidemics, famines and similar events. Further, as has been stated, the establishment of modern health conditions and living levels may give rise to a temporary surge in actual fertility as fecundity rises. In modernizing societies, pronounced fluctuations have been observed in conjunction with migration movements and economic conditions. While the taste and income effects of income growth may cancel out over the long term, they do not necessarily do so over shorter periods, and disparities between the two may be responsible for the "baby booms"

<sup>41</sup> L. Tabah, "La contraception dans le Tiers Monde", *Population*, vol. XXII, No. 6 (November-December 1967), pp. 999-1030; E. van de Walle and J. Knodel, *loc. cit.*

observed in the United States of America and elsewhere after the Second World War.<sup>42</sup>

75. One must recognize, too, that, at any given time, various groups in a society are in different circumstances, and different factors may be responsible for changes in their fertility. For example, whereas the effect of an increase in the survival prospects of children might be especially felt by those in the older reproductive ages, a change in the factors underlying desired size might have a greater effect on those in the younger ages.

76. Instead of the demographic transition model, there is need for an analytical framework sufficiently flexible to accommodate an explanation of the wide variety of historical and ongoing trends, fluctuations and differentials in the shift from pre-modern to modern fertility levels. The present framework is an attempt to meet this need.

## REPRODUCTIVE BEHAVIOUR AND THE FAMILY LIFE CYCLE\*

Norman B. Ryder\*\*

1. The purpose of this paper is to develop measures that are appropriate for studying the micro-demography of the family, to present the results of their application to three population types, and to discuss some implications of those findings. It is probably appropriate to begin with an apology for a paper which, like the present one, utilizes artificial rather than real data, and sacrifices much of the rich variety of family life in an effort to achieve precision. Yet the statistics discussed here are rarely available and where some approximations exist their quality is suspect and their coverage limited parochially. Accordingly, it seems not only worth while, but also necessary, to resort to simulation and to make partial amends by taking pains to indicate, *passim*, some of the ways in which the results of the models may depart significantly from reality.

### THREE REPRODUCTION MODELS

2. The models developed here have been designed to capture the essence of three classic demographic situations: high mortality and high fertility, here labelled "high equilibrium"; low mortality and high fertility, called "disequilibrium"; and low mortality and low fertility, called "low equilibrium". It is a demographic commonplace that the situation of high equilibrium has characterized most of man's life everywhere on earth, *mutatis mutandis*, although it would probably be more accurate to state that there have been many shifts of populations back and forth between high equilibrium and (positive or negative) disequilibrium. Recently, there has been a new scenario in many populations, with the movement from disequilibrium to low equilibrium. That kind of change may be irreversible; the major question facing the populations of the world is whether that new scenario can be made universal.

3. The first task in constructing the models was to characterize the mortality appropriate to the three situations. To represent the high mortality of the "high equilibrium" model, the female and male life tables identified as "West-3" in the Coale/Demeny collection were selected.<sup>1</sup> These tables have expectations of

life at birth of 25 for females and of 22.85 for males. To characterize the mortality of the "disequilibrium" model, "West-17", with expectations of life at birth of 60 for females and of 56.47 for males, was selected. Lastly, for the "low equilibrium" model, "West-23", which has expectations of life at birth of 75 for females and of 71.19 for males, is used. Except for numerical assumptions about the sex ratio at birth and about the distribution of completed fertility by duration and parity, all statistics reported in this paper are derivative from these life tables.

4. As the paper is concerned with families, it begins the discussion of fertility with a set of assumptions about nuptiality. Briefly and simply, a monogamous system is assumed, in which all women marry at age 20, all men marry at age 25, and there is no exposure to risk of fertility outside of marriage. The levels of fertility are selected to meet the following criteria: for high equilibrium, a level of fertility just sufficient to ensure replacement vis-à-vis the survival functions of females and males (and also the marriage and remarriage rules, as discussed below); for disequilibrium, the same level of fertility as used for high equilibrium; for low equilibrium, a level of fertility just sufficient to ensure replacement in terms of its survival functions.

5. In order to distribute fertility over the course of the family life cycle, it has been decided to work with successive marital durations, rather than ages, since the former seems a more appropriate temporal variable for family analysis. Specifically, it is assumed that gross fertility (exclusive of survival) is distributed by five-year duration groups (0-4, 5-9, . . . , 20-24) as follows: in the high-equilibrium and disequilibrium types, 7/25, 6/25, 5/25, 4/25, 3/25, respectively; in the low-equilibrium type, 7/16, 5/16, 3/16, 1/16, 0/16, respectively. Although it is obvious that one criterion for selecting these particular distributions was simplicity, they do, in fact, correspond well with various data representative of high and low fertility situations.

6. The three demographic contexts may be described as follows. High equilibrium is characterized by high fertility and mortality; the population is stationary, with birth and death rates (necessarily) equal at 42 per 1,000 per annum. The second situation, called disequilibrium to emphasize its disruptive and essentially transitory character, is identical with the first with regard to fertility, but has a much lower level of mortality. The population is stable, with a growth rate of

\* The original text of this paper (E/CONF.60/SYM.II/8) was submitted to the Symposium on Population and the Family, Honolulu, 6-15 August 1973.

\*\* Office of Population Research, Princeton University, Princeton, New Jersey, United States of America.

<sup>1</sup> Ansley J. Coale and Paul Demeny, *Regional Model Life Tables and Stable Populations* (Princeton, N.J., Princeton University Press, 1966).

3.2 per cent per annum (because the birth rate is 42 and the death rate 10). This epitomizes the lot of most developing countries. The third model, low equilibrium, is again a stationary population, with birth and death rates equal at a little less than 14 per 1,000 per annum. This resembles closely the intrinsic condition of most developed countries.

7. The basic parameters are recorded in table 1, showing for comparison two polar assumptions concerning remarriage. These statistics were developed in the following way. The high-equilibrium situation begins with the assumption that the net reproduction rate equals 1.0 (the technical meaning of replacement). The second-to-last column, child survival, is the proportion

of females surviving to marriage age. Then the net level of fertility,  $G$ , required to counterbalance child non-survival, and thus replace each woman (as of age at marriage), is the reciprocal of the product  $qS$ , where  $q$  is the proportion of births which are female (assumed to be 20/41). In order to derive the appropriate gross level of fertility,  $F$ , from the net level,  $G$ , one must know the value of  $L$ , the parental survival, since  $G = FL$ . The value of  $L$  is the weighted mean of the survival proportions in each duration, where the weights are the relative amounts of duration-specific fertility, and the individual survival proportions represent the women who are exposed to the risk of fertility by virtue of being married.

TABLE 1. REPRODUCTION PARAMETERS UNDER CONDITIONS OF NO REMARRIAGE AND COMPLETE REMARRIAGE

Condition	Gross level of fertility $F = G/L$	Parental survival $L$	Net level of fertility $G = R_0/(qS)$	Child survival $S$	Net reproduction rate $R_0$
<i>No remarriage</i>					
High equilibrium	6.4838	0.69054	4.4774	0.45786	1.0
Disequilibrium	6.4838	0.91134	5.9090	0.87010	2.5079
Low equilibrium	2.1202	0.98818	2.0951	0.97846	1.0
<i>Complete remarriage</i>					
High equilibrium	5.3608	0.83520	4.4774	0.45786	1.0
Disequilibrium	5.3608	0.95894	5.1455	0.87010	2.1821
Low equilibrium	2.1038	0.99590	2.0951	0.97846	1.0

8. The concept of the net reproduction rate has been modified to make it more useful for family demography. The net reproduction rate is conventionally described as the product-sum of the female age-specific fertility rates and the proportions of women surviving from birth to the age in question. In the present models, which are oriented to marital fertility, duration rather than age has been used; and, in effect, the survival component of the conventional net reproduction rate has been divided into two parts, parental survival (from duration zero to each successive duration within the fertile span) and child survival (from birth to marriage age, which will be duration zero for the next generation of women).

9. The data may be used to examine a question of great importance in many cultures: the probability of a male heir. Suppose a male heir is defined as a son who survives to marriage age. Then it may be shown that the proportion of women of  $N$ th parity (those who end up with  $N$  live births) who have no surviving son in that sense, is  $(1 - ps)^N$ , where  $p$  is the proportion of births which are male (21/41) and  $s$  is the proportion of male births which survive to marriage age. The value of  $(1 - ps)$  for the three models is: 0.794 for high equilibrium; 0.572 for disequilibrium; and 0.493 for low equilibrium. It is apparent that the level of mortality bears importantly on the question.

10. In order to determine the over-all proportion of women who fail to have a male heir, it is necessary

to make some assumption about the complete (live birth) parity distribution of women. After considerable experimentation, a "triangular" distribution has been chosen in which the proportion ending with  $x$  births is  $2(w + 1 - x)/((w + 1)(w + 2))$ , where  $w$  is the highest parity attained ( $w = 3F$ ). This is suitable for representation of high fertility parity distributions. For the low-equilibrium model, it was been arbitrarily assumed that the proportions ending in parities 0, 1, 2, 3, 4 are 10 per cent, 20 per cent, 30 per cent and 10 per cent, respectively.

11. The outcome of these calculations is that the proportion of marriages failing to produce a male heir, in the high-equilibrium situation, is 44 per cent. The proportion is 21 per cent in the disequilibrium context and 32 per cent for low equilibrium. Considering the high salience of this concern in many populations, the circumstances that the proportion without a surviving son, under high equilibrium conditions, is as high as 44 per cent is surely a matter of considerable importance for kinship analysis. Moreover, the circumstance that the proportion falls to 21 per cent when mortality declines and disequilibrium is produced constitutes a powerful support for continued high fertility. The value in the low equilibrium context is probably less significant from a socio-cultural standpoint, since a decline in the importance of a male heir is a likely correlate of the typical social transformations involved in the approach to a low demographic equilibrium.

12. As a methodological foot-note, it is approximately the case that the proportion of couples with no surviving son, in a high fertility situation, is  $2PQ$ , where  $P = 1/(3R_0)$ . For example, a net reproduction rate of 1 (as in high equilibrium) would with this formula give a value of  $4/9$ , which is approximately the 44 per cent calculated from a detailed parity distribution. Simply speaking, then, the probability of a male heir varies directly with the net reproduction rate. In a low-fertility situation, on the contrary, the key determinant is the variance in completed fertility.

13. Returning now to the discussion of table 1, note that the  $L$  values in the upper panel (no remarriage) are less than those in the lower panel (complete remarriage), especially for high equilibrium. If it is assumed that there is no remarriage, the consequence is that a woman departs from exposure to risk if either she or her husband dies. Thus, the  $L$  values in the upper panel represent the outcome when joint survival of husband and wife is used in developing the calculations. If, on the other hand, the assumption is that every widow remarries, and does so immediately upon dissolution of her marriage, then women remain exposed to risk so long as they survive, and the appropriate survival proportions in this case are those of the woman alone.

14. In the situation of no remarriage, a gross level of fertility of  $F = 6.5$  is needed to achieve replacement, because of the low level of child survival ( $S = 46$  per cent) and of joint parental survival ( $L = 69$  per cent). Holding this gross level of fertility constant, as in the disequilibrium model, but lowering mortality, has the consequence of propelling the net reproduction rate upward from 1.0 to 2.5. In the situation of complete remarriage, on the other hand, the gross level of fertility required for high equilibrium is  $F = 5.4$ , because the survival for the wife alone ( $L = 84$  per cent) is so much higher than that for husband and wife together. With that level of fertility, the disequilibrium situation would have a much lower net reproduction rate (2.2), the birth rate would be 36 rather than 42, and the growth rate would fall to 2.6 per cent per annum.

15. The "no remarriage" assumption is employed throughout the remainder of this paper. All societies are in fact arrayed on a continuum between the polar positions of no remarriage and complete remarriage (just as they depart more or less from universality of marriage). The "efficiency" of remarriage behaviour is a function of both the probability that a widow will remarry and the length of time between the dissolution of one marriage and the formation of the next. The relevance of the efficiency of remarriage for determining how much fertility is required for replacement varies strongly with the level of mortality. In the low-equilibrium model, for example, the respective values of  $L$  are essentially the same—98.8 per cent for no remarriage, and 99.6 per cent for complete remarriage. (Obviously, marital dissolution occurs for reasons other

than death of spouse and the incidence may be high in some countries. The question of the efficiency of remarriage after divorce is important in that context, but the subject falls outside the scope of the present paper.)

16. One concealed detail of the model casts some light on the demographic influences on male and female marriage and remarriage. The specification that all females marry at 20 and none remarry, and that all males marry at 25 does not make explicit whether there are sufficient males at age 25 to provide spouses for all females at age 20. In fact, in the populations implicit in these three types, there is an 8 per cent shortage of males in high equilibrium, a 14 per cent shortage in disequilibrium, and a 3 per cent surplus in low equilibrium. As mortality declines, the absolute difference between male and female survival diminishes, and an ever more dominant role in the relative numbers of the sexes is played by the 5 per cent surplus of males at birth. The reason the disequilibrium situation shows a departure from this general principle (which would have predicated a 1 per cent surplus of males in terms of mortality considerations alone) is that it is a stable population, growing at 3.2 per cent per annum. Accordingly, since males are five years older than females at marriage, a shortage of 15 per cent ( $1 - e^{-5(0.032)}$ ) is generated.

17. There are two directions, in a monogamous society, in which all females can be married at age 20: (a) reduction of the age difference between brides and grooms; (b) marriage of some spinsters to widowers. In the high-equilibrium situation, the first of these modifications would require reducing the age difference to zero. There are almost certainly social and economic reasons why this strategy would generally be unacceptable. In order to discuss the feasibility of the second approach, the probability of marital dissolution for each of the three population types has been calculated. The mean durations at dissolution for the three population types are 12, 14 and 16 years, respectively. It is apparent that, unless there is remarriage in the high-equilibrium context, or fusion with another household, a very substantial number of children will be raised in households with only one parent. Note also that substantially more widows than widowers are created, suggesting substantial scope for polygyny (see table 2).

TABLE 2. OUTCOME OF 100,000 MARRIAGES  
(First 25 years)

	Number of couples surviving	Number of widows created	Number of widowers created
High equilibrium . . .	31,832	38,100	30,068
Disequilibrium . . . . .	75,683	14,304	10,014
Low equilibrium . . . . .	92,802	4,825	2,373

18. Returning now to the question of the feasibility of marriage of some spinsters to widowers, in the high-equilibrium context, in order to preserve universality

of female marriage, it is apparent that, since 30 per cent of the marriages produce widowers (in the age span from 25 to 50), there is no difficulty of supplying brides with widowers to compensate for the shortage of bachelors. Indeed, the supply of widowers in a high-equilibrium society is sufficient to permit a substantial amount of remarriage of widows as well.

19. In the disequilibrium situation, on the other hand, the deficit of males is 14 per cent, and only 10 per cent of the marriages produce widowers—a proportion which is scaled down to 6.5 per cent when discounted for the growth rate. Accordingly, it would seem to be very difficult in the disequilibrium context to achieve universality of female marriage at age 20. Furthermore, one implication of a net reproduction rate of 2.51 is that the number of marriages (under a rule that marriage is universal) would increase by 151 per cent each generation. As there are external conditions which need to be satisfied in order to establish a marriage, and as other forces of change (such as increased education) may tend to delay marriage, it appears likely that the difference in age at marriage of husbands and wives may increase and exacerbate the deficit of males. In either circumstance, it is likely that the proportion of women married, in the disequilibrium situation, will be substantially less than 100 per cent. It follows also that non-remarriage of widows is much more plausible than complete remarriage. Accordingly, the level of the net reproduction rate, in the disequilibrium context has probably been over-estimated.

20. Once a marriage is dissolved by the death of a husband, there are three kinds of option available to the widow and her children:

(a) She may remarry. This may occasion a merger of two households, each with children, should she marry a widower. The fertility consequence of exercising this option is that the widow continues exposed to risk. Thus, the impact of mortality in this case is solely on the number of households, and not at all on fertility;

(b) The widow may not remarry, and choose to remain with her children in the same household. The impact of mortality in this situation is solely on fertility, and has no effect on the number of households;

(c) The widow may not remarry, but move with her children into another already existing household, probably that of her or her husband's kin. In this situation, the impact of mortality falls both on the number of households and on female fertility, because a household disappears, and the widow is no longer exposed to the risk of fertility.

21. The conventional approach to the question of household size is to describe a particular set of institutions or customs, and then determine the consequences of adhering to those customs in a particular demographic situation. However, it is worth contemplating the possibility that the primary emphasis is on achieving a household of a particular size—not too large and not

too small—and that practices are followed which, in a particular demographic context, achieve that objective, but which are abandoned when the demographic situation changes, because the desired household size is no longer achievable. There is considerable scope for modification of household size by an alteration of the distribution of the choices made by widows among the three options just discussed, by transferring children from one household to another, by the earlier or later departure of unmarried children from the household, or by the fusion or fission of existing households which have more adults than one married couple. The considerable demographic differences between high equilibrium and disequilibrium, charted in this paper, may mislead one about realistic outcomes, because their implications are likely to provoke compensatory modifications of such customs.

#### COMPONENTS OF FAMILY LIFE

22. Perhaps no concept is so often employed in demographic disquisitions as "family size"; yet the difficulties of defining and measuring it in a satisfactory way are almost insurmountable. In this section an approach is made to the question by considering the individual and joint person-years of life which are, so to speak, generated by a marriage; in the final section an attempt is made at resolution of the conundrum.

23. The most common referent of the term, family size, is in fact the gross fertility level, that is, the mean parity of a woman who survives to the end of the reproductive period. In this sense, the levels of family size are 6.5 for high equilibrium and disequilibrium, and 2.1 for low equilibrium. Aside from the quibble that this measure excludes parents from the family, there are two serious difficulties with it. The first of these is readily overcome, using procedures explained in connexion with table 1, by taking into account the extent to which parental non-survival reduces fertility per couple by using  $G$  rather than  $F$  (and add two for the parents). This measure gives 6.5 as family size in high equilibrium, 7.9 for disequilibrium and 4.1 for low equilibrium.

24. The second difficulty concerns the circumstances that the values just presented measure the frequency of persons who at any time are members of the nuclear family, but ignore the time dimension, i.e., how long they are members. If the family is to be thought of as a population, both dimensions need to be included in its quantification. To this end, table 3 has been prepared, showing the number of years of life within the family represented by each type of family member. In making this calculation, the maximum time span of membership has been set at 35 years for the parents, 25 years for the son and 20 years for the daughter. The choice of 35 years for the parents is an approximation of the length of time between their marriage and the marriage of their last child. The time lengths for children correspond with the age at marriage assumptions.

TABLE 3. YEARS OF LIFE PER PERSON WITHIN APPROPRIATE DURATION LIMITS

	Father	Mother	Son	Daughter	Weighted total
High equilibrium . . . . .	23.47	25.40	12.16	10.69	100.12
Disequilibrium . . . . .	31.25	32.34	21.74	17.86	180.85
Low equilibrium . . . . .	33.70	34.37	24.29	19.63	114.20

25. Although the rise in length of life within the designated duration spans of family participation is a simple reflection of the postulated decline of mortality, its representation in this way reveals the import of that decline for the size of the family, viewed as a population, that is, in person-years terms. The final column of the table represents a first approximation to family size in that sense. It is obtained by weighting the person-years for sons and daughters by  $pG$  and  $qG$ , respectively, where  $p$  is the proportion of births male, and then adding to the two products the person-years of parents. This provides a clear perspective on the population explosion as it is experienced at the family level: an increase in total person-years of some 80 per cent from high equilibrium to disequilibrium. As for low equilibrium, ordinarily characterized as the "small-family system", its family size is in fact appreciably

larger than that for high equilibrium, that is, larger than family size must have been throughout most of human history.

26. Before proceeding further with this exercise, one phenomenon of considerable importance in distinguishing among the three population types deserves advertisement, namely, variability. The parameters presented in this paper have the tendency of any average to conceal the distribution being summarized. The extent to which individual experience differs from average experience is itself an important social fact, entirely aside from a parallel interest in differential fertility and mortality among aggregates like social classes or ethnic groups. Table 4 shows the standard deviations and the coefficients of variation (ratio of standard deviation to mean, expressed as a percentage) for the five measures employed in table 3.

TABLE 4. STANDARD DEVIATION, AND COEFFICIENT OF VARIATION (PERCENTAGE) OF NET FERTILITY AND OF FOUR MEASURES OF PERSON-YEARS OF LIFE

	Net fertility	Length of life in specified interval			
		Father (35)	Mother (35)	Son (25)	Daughter (20)
Standard deviations					
High equilibrium . . . . .	4.31	11.56	11.55	11.62	9.26
Disequilibrium . . . . .	4.81	7.87	7.04	8.03	5.88
Low equilibrium . . . . .	1.14	4.55	3.32	4.07	2.62
Coefficients of variation					
High equilibrium . . . . .	96	49	45	96	87
Disequilibrium . . . . .	81	25	22	37	33
Low equilibrium . . . . .	54	13	10	17	13

27. In estimating the standard deviations of net fertility, the same parity distribution has been used as was described in the account of the probability of having a male heir. Since the variance of the high fertility distribution is  $G(G+1)/2$ , the coefficient of variation necessarily varies inversely with the mean. However, that mechanical effect is very small compared with the observed differences. It would show a mere decline from 78 per cent to 76 per cent in a comparison of high equilibrium and disequilibrium. The reasons for the much higher values of the coefficient of variation, and for the much greater decline from high equilibrium to disequilibrium, is that not only the within-group variance provided by the formula is included for each duration of termination of childbearing, but the between-group variance, which is considerable for the high-equilibrium situation (as could be inferred from

the high probabilities of marital dissolution reported in table 2).

28. The key finding is that considerable variability in every dimension of family size is a prominent characteristic of the high-equilibrium society. The larger the variability, the larger the proportions of very large and very small families, relative to the reported means. Otherwise stated, high mortality means a large role for chance in human affairs. Accordingly, it is likely that social customs to cope with its frequent intervention will be adopted. Among those customs, one may suggest that the extended kinship system, as a device for providing an insurance policy against the exigencies which may face any particular nuclear family, is a most important institutional development in the absence of any alternative organization for this purpose in the larger society. Furthermore, the most sensible orien-

tation of any family would be to err in the direction of too large rather than too small a family size, to avoid the probability of extinction or of falling below the critical number needed to maintain a viable household. Lastly, the solution to the problem of a household which has become too large (by some criteria of organizational or other problems associated with large size) is fission, whereas the solution to the problem of the household which has become too small is fusion. From a sociological standpoint, the former appears to be a much simpler procedure than the latter. In brief, it is suggested that one of the important props for high fertility is the variance of fertility and mortality characterizing the high equilibrium situation.

29. To conclude this discussion of variability, it is noted that, although it has been convenient from a modelling standpoint to employ one particular set of life tables in each case, implying constant probabilities of survival by age, it is highly likely that there is considerable variation in such probabilities over time, with long periods in which the average length of life may have been 40 or 50 years (rather than the average of 25 for females and 23 for males), interspersed with brief intervals in which mortality was catastrophically higher. Fertility would also be likely to follow a variable course through time. Thus, a kind of temporal variance needs to be imposed on the dispersions mentioned here, adding further force to the argument.

30. Returning to the question of the dimensions of family size, there has been considerable debate in sociology and social anthropology about how to define a family, particularly in connexion with the debate on the universality of the nuclear family. One direction of resolution of that debate is useful, because it suggests a battery of appropriate family demography measures. The point is that efforts to define the nuclear family in concrete terms have raised very considerable difficulties and have led to the suggestion that attention should be concentrated on particular relational pairs which, *in toto*, make up the constellation of role-relationships known as the nuclear family. These role-relationship pairs are, of course, husband/wife, father/son, father/daughter, mother/son, mother/daughter, brother/brother, brother/sister, and sister/sister. It is proposed to examine the quantity of life in such role-relationship pairs, in each of the three models. These dimensions of family demography may interest analysts concerned with the quality and salience of such relationships.

31. First to be considered is the husband/wife pair. Table 5 shows the mean lengths of life, individual and joint, within the first 25 years of marriage; this length

TABLE 5. INDIVIDUAL AND JOINT HUSBAND/WIFE LIFE (First 25 years of marriage)

	Husband	Wife	Joint
High equilibrium . . .	19.24	20.08	15.89
Disequilibrium . . . . .	23.40	23.79	22.31
Low equilibrium . . . . .	24.56	24.77	24.34

of time was chosen because of its importance for fertility. The sharp contrast between individual and joint survival, in the high-equilibrium situation, and the large difference between its joint value and that of the other two models, are different ways of reporting the substantial incursions made by mortality on prospective fertility.

32. One may also consider the husband/wife relationship in its totality, that is, in terms of individual and joint expectations of life of husband and wife. Immediately it is seen from this table that the marriage contract, in the high-equilibrium situation, is actually rather short, lasting, on average, about 19 years; but that, as mortality declines, the length of joint life "till death do us part" becomes progressively and substantially longer. As an interesting detail, the gap between expectation of life of the wife and the joint expectation of life remains approximately constant at 12 years (the years of widowhood) whatever the level of mortality, but the years of widowerhood, measured in a comparable fashion, become progressively fewer (as the gap between husband's and wife's expectation of life grows). (See table 6.)

TABLE 6. INDIVIDUAL AND JOINT EXPECTATIONS OF LIFE AT MARRIAGE

	Husband	Wife	Joint
High equilibrium . . .	26.55	31.25	19.20
Disequilibrium . . . . .	41.59	48.44	35.84
Low equilibrium . . . . .	48.72	56.59	45.22

33. Although much of the discussion of the family centres on reproduction, it seems more appropriate to regard the family's central function as socialization, since many alternative social arrangements for procreation are imaginable, but the family as a design for child-rearing has unique properties. In table 7, we examined the years available for parent/child interaction in each of the models for the four nuclear family combinations. The total possible years in each case are 20 if the daughter is involved and 25 if the son is involved. For the purposes of calculating parental survival, they are located at their mean ages of fertility (corresponding in the three models to durations 6.87, 10.03 and 6.86, respectively, to which are added 20 years for the mother and 25 years for the father). The table contains in the last column a weighted sum, divided by four because of the doubly duplicate representation. The weights are the mean numbers of sons and daughters in each appropriate case. This table shows a tripling of the exposure to the parent/child relationship, between high equilibrium and disequilibrium. Furthermore, there is essentially no difference in family size, so measured, between the high equilibrium and the low equilibrium situations. One ventures the speculation that the magnitude of parent/child experience is a simple function of the net reproduction rate.

TABLE 7. JOINT PERSON/YEARS OF PARENT/CHILD EXPERIENCE

	Mother/ daughter	Father/ daughter	Mother/ son	Father/ son	Weighted sum/4
High equilibrium . . .	9.54	9.21	10.47	9.86	21.89
Disequilibrium . . . . .	17.14	16.72	20.52	19.76	63.34
Low equilibrium . . . . .	19.47	19.28	23.98	23.62	22.67

34. The final joint survival presentation considers sibling relationships. Here again there are four possible combinations (elder and younger brother and sister). An average difference between siblings of five years of age is specified. In keeping with the assumption that males remain within the family for a maximum of 25 years and females for 20 years, the length of time during which survival is counted becomes 20 years if the elder child is a male and 15 years if it is a female. The weighting scheme for the final two columns re-

quires explanation. There are three components to each weight: (a) the total number of sibling combinations, which, following the parity distributions discussed above, is  $G(3G-1)/4$  for the high-fertility models, and 1.8 for low equilibrium; (b) the proportion of elder children surviving to age five; (c) the probabilities of the different sex combinations ( $pp$ ,  $pq$ ,  $qp$  and  $qq$ , where  $p = 21/41$  is the probability of a male birth). The means and their weights are presented in table 8. In some senses, this is the most remarkable table in the

TABLE 8. JOINT PERSON/YEARS OF SIBLING EXPERIENCE

Elder child/ Younger child	Brother/ Brother	Brother/ Sister	Sister/ Brother	Sister/ Sister	Weighted total	Mean years per child
<i>Mean years of experience</i>						
High equilibrium . . . . .	9.92	10.38	8.02	8.38	67.23	15.02
Disequilibrium . . . . .	17.31	17.71	13.22	13.43	339.64	57.48
Low equilibrium . . . . .	19.42	19.56	14.64	14.74	30.20	14.41
<i>Number of combinations</i>						
High equilibrium . . . . .	1.86	1.77	1.90	1.81		
Disequilibrium . . . . .	5.71	5.45	5.55	5.28		
Low equilibrium . . . . .	0.46	0.44	0.44	0.42		

collection. Within the high-equilibrium model, the total amount of sibling interaction is modest, despite its high fertility. Within the disequilibrium situation, which has the same gross fertility, the amount of sibling time for interaction is multiplied more than fivefold. Lastly, in the low-equilibrium population, the total amount of sibling time for interaction is, in comparison, minuscule. The mean years of sibling interaction per child are, however, approximately the same in the two equilibrium situations, but much larger in the disequilibrium situation. As was suggested for the comparable parent/child calculation, it is surmised that this is a simple function of the net reproduction rate.

#### THE MEASUREMENT OF FAMILY SIZE

35. In the foregoing text, measures of family size have been criticized which consider only the frequency with which persons can be found at any time within the bounds of the family definition, and the importance of incorporating the time dimension in the calculation has been suggested. The results of table 3 provided a measure of 100 person-years for high equilibrium, 181 person-years for disequilibrium and 114 person-years for low equilibrium. Although that measure has the preferred orientation, it is not without defects. The

principal problem is that some of the years so counted for children may in fact be spent outside the family, in orphanhood (between the time of dissolution of their family of orientation and the time of formation of their family of procreation); and some of the years so counted for parents may be spent outside the time frame of the family as ordinarily understood (as, for example, in widowhood after the last child has married).

36. Then there was an examination of three facets of family composition—husband/wife, parent/child, and sibling/sibling joint person-years. Parent/child interaction is a sufficient but not a necessary condition for the existence of a family; husband/wife interaction is sometimes sufficient but never necessary; sibling/sibling interaction is neither necessary nor sufficient. The trouble with these component parts of the meaning of family life is that the strands of joint experience for each component overlap in time those of the other components, so that the family in its totality is, arithmetically speaking, something less than the sum of its parts. Lastly, the dimension of the measure is an unfamiliar one; the idea that a person who lives 70 years represents a population size of 70 (because population size is a sum of person-years) has not yet become familiar.

37. Resolution of the problem requires a clear definition of the nuclear family, so that one can identify unequivocally whether the family survives over any interval of time. A definition is going to be used here which is current in the literature on the family, but perhaps not employed for measurement purposes. A family will be considered as surviving so long as it contains at least one parent/child pair or, failing that, if it contains the possibility of a parent/child pair because both spouses survive and the wife is below her maximum duration of fertility. Thus, a husband and wife would be counted as a family in the part of their marriage prior to childbearing, but not after the last child had left home; two or more siblings would not constitute a family unless at least one parent was present.

38. A system of calculations has been developed to determine the length of life of a family, so defined. The essence of the procedure is as follows: Suppose first that both husband and wife survive to the maximum duration of childbearing. Thus, the family has survived at least as long as that duration, and its subsequent sur-

vival in each successive interval is the product of the probability of survival of at least one of the parents, and the probability of survival of at least one of the children. The formula for the duration-specific probability of survival is  $(1 - Q_{FA}Q_{MO})(1 - Q_{CH}^N)$ , where  $Q_{FA}$ ,  $Q_{MO}$  and  $Q_{CH}$  are the respective individual survival probabilities of husband, wife and children, and  $N$  is the number of children alive at the beginning of the duration. Note that child survival requires not only remaining alive, but also remaining within the age span of children. Should only one spouse survive the duration in question, the subsequent probability of family survival will be the product of the survival probability of the remaining spouse, and the child survival component as before. The latter formulation also applies to the determination of the duration-specific probability of family survival in the situations in which either the husband or the wife has died before the end of the fertile period. The results of this procedure are presented in table 9. For assistance in interpreting these results, the data in table 10 have been found to be helpful.

TABLE 9. LENGTH OF FAMILY LIFE

	<i>Marriages surviving to end of fertile period</i>		<i>Marriages dissolved before end of fertile period</i>		<i>Total Mean</i>
	<i>Proportion</i>	<i>Mean</i>	<i>Proportion</i>	<i>Mean</i>	
High equilibrium . . . . .	0.31832	37.63	0.68168	24.48	28.67
Disequilibrium . . . . .	0.75683	42.01	0.24317	33.87	40.03
Low equilibrium . . . . .	0.95531	31.81	0.04469	30.09	31.75

TABLE 10. MEAN DURATION AND CHILD PARITY AT TIME OF TERMINATION OF WIFE'S FERTILITY

	<i>Marriages surviving to end of fertile period</i>		<i>Marriages dissolved before end of fertile period</i>	
	<i>Mean duration</i>	<i>Mean child parity</i>	<i>Mean duration</i>	<i>Mean child parity</i>
High equilibrium . . . . .	25	2.75	11.63	2.10
Disequilibrium . . . . .	25	4.89	13.92	3.71
Low equilibrium . . . . .	20	2.07	11.70	1.61

39. In table 9 it is seen that the disequilibrium situation involves a substantially longer family lifetime than either of the equilibrium situations. The determinants of the length of family life may be briefly indicated. First in importance is mortality. The high level of adult mortality, in the high-equilibrium situation, forces premature termination of fertile life. That enhances the probability that the family will die, because one parent is less likely to survive than either of two parents, and it reduces the probability that at least one child will survive, by reducing the total number of children. Obviously, the high level of child mortality is prejudicial to long family life. The second determinant of length of family life is the level of fertility. The low equilibrium population has substantially higher survival

probabilities than the disequilibrium population, on an individual basis, but the much higher child parity of the latter is a safeguard against termination of the family by child death. High fertility is the principal source of the long family lifetime in the disequilibrium context. The final determinant is the duration distribution of fertility. The mean duration of gross fertility is 10.5 in the high-equilibrium and disequilibrium situations, but 6.875 in the low-equilibrium model. This circumstance, in combination with low fertility, makes for a relatively short family lifetime in low equilibrium. (The lower the mean duration of fertility, the lower the average age of the child at any duration, and therefore the shorter the interval until the child leaves home. Obviously, in the low-equilibrium context, child survival

is essentially 100 per cent, and the "deaths" of children are almost all a consequence of their arrival at marriage age.)

40. One by-product of the calculations just presented is table 11. The length of married life is the joint expectation of life of husband and wife subsequent to marriage. The meaning of this table is that for the last 9.47 years of its existence, the high-equilibrium family is headed by only one parent; that is almost one third of the family's total lifetime. Likewise, in the disequilibrium situation, although the length of married life has increased substantially, so has the length of family life, and the disequilibrium family is headed by only one parent for the last 4.19 years of its existence. Only with low equilibrium does one find a situation in which, partially because of improved survival, but mainly because of a smaller number of children born at an earlier duration, there is a considerable length of married life after the family, in the sense in which the term is used here, has gone out of existence. This is the so-called "empty nest" phase of the family life cycle. It is a unique characteristic of low equilibrium.

TABLE 11. LENGTH OF MARRIED LIFE AND LENGTH OF FAMILY LIFE

	<i>Length of married life</i>	<i>Length of family life</i>	<i>Difference</i>
High equilibrium . . . . .	19.20	28.67	- 9.47
Disequilibrium . . . . .	35.84	40.03	- 4.19
Low equilibrium . . . . .	45.22	31.75	+ 13.47

41. Preliminary to the calculation of mean family size, of which the computation of length of family life is a prerequisite, an estimation has been made of the proportion of child life which is lost to family life because the children in question have been orphaned.

TABLE 13. LENGTH OF FAMILY LIFE OF FAMILY MEMBERS, AND, IN PARENTHESES, THEIR FREQUENCY

(Years)

	<i>Father</i>	<i>Mother</i>	<i>Sons</i>	<i>Daughters</i>
High equilibrium . . . . .	20.98 (1)	22.17 (1)	11.00 (2.29)	10.02 (2.18)
Disequilibrium . . . . .	34.54 (1)	36.26 (1)	21.46 (3.03)	17.75 (2.88)
Low equilibrium . . . . .	30.28 (1)	30.77 (1)	24.25 (1.07)	19.62 (1.02)

and in different ways for different categories of family member. For fathers and mothers, the frequency category is obviously fixed; but the number of years is longer in the disequilibrium situation than in either equilibrium situation because larger numbers of children, born at a higher average duration, imply longer family life for the parents. For sons and daughters, the mean number of years of family life per child approaches a maximum (25 for sons and 20 for daughters) in the low-equilibrium situation, but the

This calculation requires a comparison of the total number of person-years of child life, with the number of person-years of child life within the family (the deficit being attributable to the deaths of both parents before the child reaches marriage age). The results are presented in table 12. These proportions indicate

TABLE 12. PERCENTAGE OF CHILD LIFE LOST TO THE FAMILY BECAUSE OF ORPHANHOOD

	<i>Sons</i>	<i>Daughters</i>
High equilibrium . . . . .	9.6	6.3
Disequilibrium . . . . .	1.3	0.6
Low equilibrium . . . . .	0.2	0.1

the amount by which the weighted total of person-years presented in table 3 must be discounted because of termination of the family prior to the sons and daughters reaching marriage age. Note that the proportions are lower for daughters than for sons, because daughters reach marriage age five years earlier than sons. The phenomenon of orphanhood is obviously an important characteristic of the high-equilibrium situation.

42. With these data in hand, it is possible to calculate the amount of family life contributed by each family member, here specifying that the person-years of survival for father and mother are, as a maximum, not the arbitrary 35 years used in table 3, but the actual length of family life as just determined. The person-years of survival of sons and daughters, from table 3, have been reduced by the orphanhood proportions in table 12. The results are presented in table 13, which shows the mean number in each category as well as the mean length of time each category spends in the family. The data of table 13 show the dual sense in which families have different sizes in the three models,

number of children is only one third of those in disequilibrium populations. The length of family life of sons and daughters is very low in the high-equilibrium situation because of high child mortality, exacerbated by orphanhood.

43. Lastly, table 14 presents the measurement of mean family size. The key result is contained in the third column; it is the ratio of the first column to the second. The first column is the weighted sum of the values in table 13; the second column comes from

TABLE 14. MEAN FAMILY SIZE

	<i>Total person-years</i>	<i>Length of family life</i>	<i>Mean family size</i>	<i>Mean numbers of parents</i>	<i>Mean numbers of children</i>
High equilibrium .....	90.27	28.67	3.15	1.51	1.64
Disequilibrium .....	186.93	40.03	4.67	1.77	2.90
Low equilibrium .....	107.12	31.75	3.37	1.92	1.45

table 9. For purposes of discussion, mean family size is subdivided, in the last two columns, into mean numbers of parents and children.

44. The findings in table 14 will probably surprise those who infer from the coexistence of high fertility and low mortality that the disequilibrium context is one of large families. While it is true that the value of 4.67 is large in relative terms, it scarcely seems so in absolute terms, especially when viewed from the perspective that the family, by definition, must have at least two members. A large number of person-years is involved in the disequilibrium family, but those person-years are spread out over 40 years of time. Nevertheless, mean family size is still 50 per cent larger than in the high-equilibrium context, almost entirely because of expansion of the child component. Similarly, the chief contrast between disequilibrium and low equilibrium is that the average family in the latter has only one half as many children. Once again, the "small-family system" epitomized by low equilibrium in fact yields a somewhat larger family size than does high equilibrium.

45. Measures of family size, like any other measure, should be designed in different ways to serve different purposes. It would appear from the literature that one of the most important facets of family size is the implicit magnitude of the dependency burden whenever there are many children. In table 15, two calculations are shown which are relevant to that point.

TABLE 15. TWO MEASURES OF FAMILY DEPENDENCY

	<i>Child/parent ratio</i>	<i>Consumer/producer ratio</i>
High equilibrium .....	1.09	0.62
Disequilibrium .....	1.64	0.72
Low equilibrium .....	0.76	0.40

46. The child/parent ratio is derived from the last two columns of table 14. The consumer/producer ratio is calculated by subdividing child life into that part prior to age 15, during which the child is considered as a net consumer and allocated to the numerator of the ratio, and that part subsequent to age 15, during which the child is considered as a net producer and contributor to family income, and therefore allocated to the denominator of the ratio (along with the parents). The consumer/producer ratio provides a quite different perspective on the question of dependency from that suggested by the child/parent ratio. Although the consumer/producer ratio is higher for disequilibrium than

for high equilibrium, it is higher by only one sixth, which scarcely seems a large enough increase to characterize the disequilibrium family as overburdened by its continued high fertility. Furthermore, as suggested previously, there are demographic reasons for thinking that the level of fertility stipulated for the disequilibrium situation is too high; somewhat different assumptions about relative marriage and remarriage patterns in high equilibrium and disequilibrium, respectively, would reduce still further the relative rise in the consumer/producer ratio. On the other hand, this calculation does not consider the distribution of person-years in the numerator and denominator of the ratio, with respect to time. In the period prior to the time the eldest child turns 15, the consumer/producer ratio would reach very high levels in the disequilibrium family. This is the kind of family population pressure which might induce parents to terminate their childbearing at a lower parity.

47. A comparison of the two columns in table 15 indicates that, although there is a 50 per cent rise in the ratio of children to parents between the high-equilibrium and the disequilibrium situations, the increase in dependency, as measured by the ratio of consumers to producers, is only 16 per cent. The small magnitude of the latter figure deserves further discussion because it appears to conflict with accepted wisdom about the consequences for dependency when mortality decline is unaccompanied by fertility decline. The customary measure of dependency is the ratio of the population under age 15 and over age 65 to the remainder of the population. Since this paper is not concerned with the problem of old dependants, comments are restricted to the ratio of persons under 15 to those between 15 and 65. For the three populations implicit in the models, the child-dependency ratio is 0.54 for high equilibrium and 0.85 for disequilibrium, an increase of 59 per cent.

48. There are two important reasons for the discrepancy between a 59 per cent rise in dependency, as measured conventionally, and a 16 per cent rise, as measured in table 15. First, the denominator of the conventional ratio encompasses all persons between the ages of 15 and 65, whatever their family status, whereas the denominator used in the calculations of the consumer/producer ratio in table 15 is limited to those with the status of family member as defined above. One implication of the lengthening of family life from 28.67 years in high equilibrium to 40.03 years in disequilibrium is an increase in the proportion of adult years (prior to age 65) which are allocated to the producer

side of the family budget. Secondly these micro-demographic models of family life exclude from consideration a most important aspect of the macro-demographic context, namely, the increase in the number of families which is implicit in a net reproduction rate of 2.51. The point is that, although the average value of the consumer/producer ratio in disequilibrium, over the entire 40 years of family life, is 0.72, the ratio is much higher than that in the time before the eldest child turns age 15. Since a rapidly growing population will have a disproportionately large number of families at early marital durations, the cross-sectional calculation, which is obviously the relevant one from the standpoint of the society as a whole, will show a higher burden of dependency than any one family would average over its lifetime.

49. From the standpoint of the individual family, the disequilibrium situation shows itself in two forms. On the one hand, the consumer/producer ratio of 0.72 over all is actually a balancing of a high dependency burden in the early years of the family against a low dependency burden in the later years. On the other hand, efforts to increase productivity and to compensate for the higher ratio of consumers to producers tend to be frustrated by the increased numbers of other families in the same situation.

#### CONCLUSION

50. The calculations presented in this paper provide a cogent explanation for the persistence of high fertility, despite a substantial decline in mortality. Comparison of the disequilibrium family with its precursor, the high-equilibrium family, is very much to the advantage of the former. The proportion of fathers without a male heir is reduced by one half, the length of joint married life increases from 19 to 36 years, each child lives almost twice as long within the family setting, the variability of each dimension of family life is reduced substantially, as is the pernicious role of chance. There are three times as many opportunities for parent/child interaction and four times as many for sibling interaction. The proportion of family life in which there is only one surviving parent is cut from one third to one

tenth. Truly the high-equilibrium situation is "nasty, brutish and short", and its disequilibrium successor must seem like a boon by comparison.

51. The outstanding disadvantage of the disequilibrium family in the tables presented above is the consumer/producer ratio, which is 16 per cent higher than in the high-equilibrium situation. Taken at face value, such an increase might be regarded as an acceptable price to pay for the list of benefits enumerated in the preceding paragraph. But the qualifications to this observation are important. First, there is a substantial lag of producer-years behind consumer-years, and the source of borrowing is unclear. Secondly, the problems of the family in a disequilibrium population are exacerbated by the circumstance that the number of families competing with each other for a place within the socio-economic aggregate is increasing by 151 per cent per generation.

52. This is a prime example of the classic conflict between the perception of the situation from the micro-level, and the perception from the macro-level (which, in a methodological context, has been the prime purpose of this paper). But the point is far from academic, since the locus of the decision process, which will turn disequilibrium into low equilibrium by reducing fertility, is on the micro-level. There are points of particular strain within the disequilibrium situation, in particular, young adults prior to marriage and couples all of whose children are still young. Because of the correspondence between their micro-demographic perceptions, and the macro-demographic evaluation of the costs of rapid growth, these would appear to represent prime targets for policies and programmes.

53. Although the demographic exercises that constitute this paper have been illuminating to the writer, and may be instructive to others as well, they remain crude over-simplifications. The complexity of interpenetration of reproductive institutions and family population processes and structures lies well beyond the reach of mere deduction. This paper will have served its purpose if it provokes not merely an extension of simulations to encompass more elaborate contingencies, but the energetic pursuit of hard data concerning real families.

## SOCIO-CULTURAL PATTERNS, FAMILY CYCLE AND FERTILITY \*

Moni Nag \*\*

### BACKGROUND INFORMATION

"The structure and dynamics of the family are determined by births and in-movements, deaths and out-movements. This may seem demographic in process and therefore a statement of the demographic determination of family formation and dynamics; it is not. The births and deaths that occur in the family group may be viewed with equal felicity as consequences of the rules that accord individuals to family units, the sex relations of the couples, and the extent to which decision-making and adaptation include the production of new life."<sup>1</sup>

1. Despite a wealth of published books and articles on the family, the mechanisms of the relationships between socio-cultural factors, the family processes and fertility have not been investigated adequately. Anthropologists have studied kinship systems in depth, mostly in non-industrial societies, but have done very little in the way of relating such systems to fertility. Furthermore, there is rightful reluctance among anthropologists to distinguish too sharply between "family" and "kinship".<sup>2</sup> Sociologists have in the past focused more on the nuclear family than on wider kinship networks, largely because of the nature of the societies in which they worked. Their work on fertility has for the most part connected individual socio-cultural factors with fertility outcomes, thus ignoring the family as mediator or individual family interaction processes with reproductive behaviour, thereby failing to provide an aggregate picture.<sup>3</sup> For their part, demographers have con-

centrated on the end-products of such interaction—such as birth rates and migration—without relating these to family and kin. Their interest has been mainly on the aggregates obtained from census and vital registration records, which usually take individuals as the unit. The lines of distinction are, of course, blurring.

### Purpose and scope

2. This paper attempts to identify the important interrelationships between socio-cultural variables and family cycle, with special reference to fertility. Attention is given to the beliefs and value systems, social organization, technological levels and other related factors, and their interrelationship with the formation, development and dissolution of the family. Cases are drawn from the ethnographic, sociological and demographic literature covering international conditions and variations, both current and past.

3. After setting down a working definition of "family" and briefly discussing ascribed functions of the family, this paper proceeds to make a case for the cyclical nature of the family. For the sake of organization, phases in the family cycle are considered in three broad categories: (1) marriage or union: family formation; (2) family development; and (3) divorce and death: family dissolution.

4. One is tempted to assume the biological model of a heterosexual couple reproducing, their offspring growing into adults and the parents dying. In fact, it is known that the family is socially as well as biologically defined; and that fictive-kin, in some societies, may be more important than actual biological kin. Moreover, death can interrupt a family before it has completed the ideal biological cycle. It is, therefore, acknowledged from the outset that the above-mentioned categories are by no means mutually exclusive: marriage may not signal the formation of another family if the newlyweds are to live in the extended family household where one of them has spent his or her childhood; likewise, the divorce of a young mother with a small child does not prevent the mother-child dyad from being called a family. Clearly, there is no inevitable progression from one phase to the next; one may marry twice before having children, choose not to marry at all or in the married state remain childless.

sented at the workshop, "Como mejorar programas de planificación familiar en América Latina", Bogotá Colombia, 24 May-4 June, 1971.

5. Despite these and other limitations, the general concept of family cycle is, none the less, extremely important because it leads one away from thinking in terms of static ideal family types and towards an appreciation of actual process. This paper discusses particular socio-cultural variables in terms of the phases of the family cycle for which they appear most relevant. In other words, the paper is topically organized around family-cycle variables, and socio-cultural variables are discussed only in connexion with these. Of course, the family is very much part of its socio-cultural setting, in fact, difficult to untangle from it. The interaction is, therefore, much more complex than would appear from the heuristic organization of materials that follows. Furthermore, both socio-cultural and family-cycle variables are subject to external political, economic and demographic constraints, which are, for the most part, outside the scope of this paper. Consequences for reproduction are also discussed in terms of phases in the family cycle.

#### *Definition of family*

6. The term "family" is employed here with full recognition of the controversy surrounding the question of its universality as well as of the existence of other terms, such as "household" and "domestic group", which have been distinguished from it.<sup>4</sup> Family is used here in accord with Taeuber's definition as, "Those related persons who live together within a household, usually with common eating as the criterion of co-living".<sup>5</sup> This definition has limitations. For example, one author has stated, "The family is not merely a residential group or a household, it is a system of relationships, rights and duties and the norms that the members try to live up to".<sup>6</sup> While kin interaction can hardly be dealt with in the mass collection of census or survey data, its importance should not be overlooked in the design of community studies.

7. The term "domestic group" has been used by some anthropologists in discussing the way in which

<sup>4</sup> Most authors view the household and domestic group as synonymous, although important exception has been taken to this. See J. R. Goody, *loc. cit.*, p. 106. According to the definition recommended as an international standard, "a household consists of a group of individuals who share living quarters and their principal meals". See *Multilingual Demographic Dictionary, Population Studies*, No. 29 (United Nations publication, Sales No. 58.XIII.4), p. 4. For complexity involved in the definition of household, see Valdecir Freyre López, "El estudio de la familia con base en los censos de población", in *Conferencia Regional Latinoamericana de Población*, Proceedings of the Conference, held at Mexico City, August 1970 (Mexico, 1972), vol. 1, p. 269.

<sup>5</sup> I. B. Taeuber, "Change and transition in family structures", *loc. cit.* p. 41. It is different from the following definition stated in the *Multilingual Demographic Dictionary*: "The family is a different unit which must be carefully distinguished from the household. It is defined primarily by reference to relationships which pertain to or arise from reproductive processes and which are regulated by law or by custom.", p. 5.

<sup>6</sup> I. P. Desai, "Family research in South East Asia—an approach (with special reference to India)", in Family Planning Association of India, ed., *Changing Family Patterns of Asia*, report of the Proceedings of the XVII International Conference on the Family, held at New Delhi, 11-17 December 1966 (Bombay, 1966), pp. 196-199.

the development cycle influences family and household. It is an over-all term for three main kinds of units, namely, the dwelling unit, the reproductive unit and the economic unit. The economic unit may cover persons engaged in the process of consumption. In some development cycles, they are quite distinct.<sup>7</sup> Although the concept of domestic group introduces an element of flexibility in some kinds of analysis, it is extremely difficult to use it for the purpose of this paper.

#### *Role and function of the family*

8. In what is perhaps the classic anthropological treatise on the subject, the claim is made that "the nuclear family is always recognizable and always has its distinctive and vital functions—sexual, economic, reproductive, and educational".<sup>8</sup> A distinguished sociologist has also defended the universality of the nuclear family, based on the two functions: socialization of children; and the socio-psychological integration achieved in the balancing of personalities in the conjugal relationship.<sup>9</sup> Examination of the ethnographic literature provides significant exceptions to these generalizations.

9. Among the Masai and Chagga of East Africa, for young men the sexual function is not limited to the family unit; since their function as warriors precludes marriage for that period of their lives, they are permitted promiscuous relations with young women.<sup>10</sup> A review of the literature on Caribbean families makes it obvious that, despite the persistence of the ideal of the nuclear family, the prevalence of other family types is as high as 40 per cent.<sup>11</sup> The woman-headed household, among Guiana Negroes and the Black Carib, diminishes the force of the functional argument for the nuclear family based on the husband's economic participation in the household and the psychologically important function of the shared conjugal relationship. Unmarried sisters and their children often can be found living in the same household with their brothers and mother and receiving male visitors for sexual relations. It has, therefore, been suggested that elemental familial relations are dyadic rather than based on the nuclear family.<sup>12</sup>

White, in Celebration of his 60th Birthday and his 30th Year of Teaching at the University of Michigan* (New York, Thomas Y. Crowell, 1960), p. 36.

10. In other societies, although the biological nuclear family could be found to reside together, it did so in the context of a larger extended family, and could only be artificially separated from this larger grouping, to be identified as being primarily responsible for the socialization of children.<sup>13</sup> Elsewhere, the responsibility for socialization varies with the age of the child; among the Ashanti, the child is socialized at one point by a consanguineal unit comprised of its mother and her brother, and at another point by the conjugal unit of its mother and father.<sup>14</sup>

11. In modern industrial societies, few parents would think of formally educating their children. The schools, television and peers have taken over much of this function. The modern shift of functions from the family to other specialized social agencies has important consequences for reproductive behaviour.<sup>15</sup>

12. The case against universal functions of nuclear or other types of family should by no means diminish the basic proposition that in every society the family serves significant—if varying—social requisites. It is widely maintained that the family is the basic social unit, and one popular anthropologist has gone so far as to state that, despite recurrent talk of troubled times for the family in periods of revolutionary change, “It is the only institution we have that doesn’t have a hope of disappearing.”<sup>16</sup> In evolutionary terms, the family served as the mechanism to ensure survival of the young so that they might live to reproduce and maintain the human species. The offspring of primates are born helpless and require both nurture and protection; the co-operation of females nursing and caring for children and males defending females and their children from predators evolved out of necessity.<sup>17</sup> Today, it appears that some social institutions which were designed in large part to ensure reproduction and ward against high mortality by protecting and providing for the rearing of children, are already changing or need changes to allow the societies to adapt themselves to their environments.

#### *Feedback mechanisms*

13. Although the decision to procreate can be made

Fried, ed., *Explorations in Anthropology; Readings in Culture, Man, and Nature* (New York, 1973), p. 302; originally published in *Journal of Marriage and the Family* (United States of America), vol. 33, No. 4 (1971), pp. 760-771.

outside of the settings of marriage and the family, for the most part, societies exercise control over reproduction through these institutions. The line of causation is not simply one-way, with socio-cultural conditions determining family formation and dissolution, and these family processes in turn influencing reproduction. Social scientists have become increasingly aware of how demographic mechanisms can limit social forms.<sup>18</sup> Still, the limitation of possibilities should not be confused with “demographic determinism”; the timing and number of births are themselves very much a function of role prescriptions; economic considerations, such as the perceived costs and benefits of children; religious mores; rules of descent inheritance and so on.

14. In actuality, feedback mechanisms among family, socio-cultural variables and fertility operate in a complex manner. For instance, new attitudes of equality for women affect the availability and desirability of alternatives to marriage, which, in turn, may affect reproductive behaviour. Within marriage, communication patterns between husbands and wives, parents and children, and between in-laws are also likely to be modified if females become more independent. If fertility is lowered as a result, then the future age distribution of the population will change as well. A new demographic profile, together with modified family size, means different intra-family roles, a changing pool in the proportion of potential marriage partners and an altered job market. In other words, changes in any of the socio-cultural, familial or demographic variables can have repercussions for others.

15. The importance attached to each of the variables can also change with time. Whereas high fertility in the absence of birth control and high mortality in the absence of medical care may have once played the major part in determining population profiles, today new roles and ambitions may be the more significant factors determining population growth. Of course, to suppose that families act and react in a fashion automatically synchronized with changes in the social and demographic scene would be to misread reality. Time lags, even lasting generations, between the occurrence of such social changes and responses in terms of modified reproductive behaviour may frequently result from the persistence of high fertility norms long after economic reality would proscribe them.<sup>19</sup>

<sup>18</sup> See Peter Laslett, “Introduction: the history of the family”, in Peter Laslett and Richard Wall, eds., *Household and Family in Past Time* (London, Cambridge University Press, 1972), p. 58. The same point is made by Godelier, who regards interdisciplinary co-operation among the social sciences as a necessary prerequisite to understanding complex interactions. See Maurice Godelier, “Quelques remarques théoriques sur les rapports entre famille, population et société” (E/CONF.60/SYM.II/10), paper prepared for the United Nations Symposium on Population and the Family, Honolulu, 6-15 August 1973.

<sup>19</sup> Reuben Hill, “The family and population change”, in Arthur A. Campbell and others, eds., *The Family in Transition*, Fogarty International Center Proceedings No. 3 (Baltimore, Maryland, National Institutes of Health, 1971), p. 23.

16. The family, thus seen, is not merely a passive filter through which changes in population are wrought by socio-cultural variables. As the locus where decisions about reproduction are made, it can be viewed as more a "force of change than an adaptive institution", as a nexus whose members are "not merely spectators but actors".<sup>20</sup> The family "acts" in its effects upon demographic variables, just as changes in these can modify its size, composition and interaction; likewise, altered socio-economic opportunities affect stages of child dependency, marriage rates, migration and so on.

17. Intra-familial communication as a key to decisions about reproduction should be further investigated. Many questions come to mind: whether it is true that modernization is dependent upon delayed marriages and birth control, as has been suggested;<sup>21</sup> the way in which the speed of the demographic transition affects social change;<sup>22</sup> and determination of the thresholds below which consumption desires compete with family size.<sup>23</sup> All of these areas have received some attention in the literature, but thus far there has been a failure to integrate the knowledge or to provide an operational basis for predicting future trends.<sup>24</sup>

#### MARRIAGE UNION: FAMILY FORMATION

18. Marriage is a major cultural mechanism to ensure the formation, development and continuity of family.<sup>25</sup> It should be distinguished from casual mating or union of man and woman entered into primarily for the purpose of sexual gratification. Although marriage in all societies provides a legitimate means of sexual

gratification, it has other and more important social functions similar to those of family. Levi-Strauss<sup>26</sup> has gone to the extent of stating that "among most people, marriage has very little to do with the satisfaction of the sexual urge, since the social set-up provides for many opportunities which can be not only external to marriage, but even contradictory to it". According to him, two fundamental functions of marriage, at least in societies with primitive technology, are: (1) sexual division of labour originating more from social and cultural than from biological considerations; (2) establishment of mutual dependency between families through the prohibition of incestuous marriages.

#### Definitions, types and forms

19. Although marriage is a well-defined and legally recognized institution in many societies, it is extremely difficult to formulate a definition which would apply to all the institutions commonly referred to as marriage by ethnographers. In *Notes and Queries in Anthropology*, a standard reference book, the following definition was given in 1951: "Marriage is a union between a man and a woman such that children born to the woman are recognized legitimate offspring of both parents".<sup>27</sup> Several limitations of this definition have been subsequently pointed out. It has been argued that the woman-marriage-to-a-woman among the Nuer of Africa has legal provisions strictly comparable to those of simple marriage between a man and a woman.<sup>28</sup>

20. The criterion of legitimacy of offspring in the above-quoted definition of marriage has generated a stimulating controversy among the anthropologists in the past two decades, and quite a bit of it is centred around the Nayar caste of south-west India—a borderline case for theorists of kinship. As a result, reference to the Nayar family and marriage, as they existed in the eighteenth century prior to the British occupation of the area, is very common in the textbooks on kinship or cultural anthropology. A brief description of the Nayar case would be helpful in illustrating the wide range of possible variations in human societies concerning the topics of main concern in this paper.<sup>29</sup>

21. The Nayar caste was divided mainly into four ranked subdivisions characterized by different political functions. The following description relates primarily to the lowest subdivision, which consisted of several sub-

<sup>25</sup> In societies emphasizing solidarity of lineal kin-groups over marital solidarity and extended family systems, family formation is scarcely a meaningful concept. But in other societies, a family is usually formed through marriage or parenthood. In most societies, it is thought proper that marriage should precede pregnancy. See Robert F. Winch, "Family formation", in David Sills, ed., *International Encyclopedia of Social Sciences* (New York, Macmillan, 1968), vol. V, p. 1.

<sup>29</sup> The description has been abstracted mainly from Kathleen Gough, "The Nayars and the definition of marriage", *loc. cit.*, pp. 365-377.

castes of commoner Nayars. Each village had from four to seven exogamous matrilineages of a single subcaste. Men of these subcastes were trained as professional soldiers and usually were absent from the village for part of each year in connexion with military activities. Only the matrilineal property-owning units (*Karanavan*) consisting of woman and children remained in their ancestral homes. One characteristic feature of the Nayar kinship system was that each lineage was linked by hereditary ceremonial ties with two or three other lineages. Every few years each lineage held a ceremony at which all pre-puberty girls, aged from seven to 12, were ritually married to men belonging to its linked lineages. After this ritual marriage (*talikettukalyanam*), each couple was secluded in private for three days during which sexual relations might or might not take place. The ritual husbands then left the house and had no further obligations to their ritual wives. A ritual wife also had no further obligation to her husband, except one which was very important: at his death she and all her children (whoever might be their genitor) had to observe a death-pollution ceremony for him. The ritual marriage was essential for a girl and marked various changes in her social position. The most important among them, perhaps, was that as she grew old enough she received as visiting husbands a number of men belonging to her subcaste or higher subcaste/caste. This kind of visiting relationship (*sambandham*) was strictly forbidden between any Nayar woman and a man belonging to a subcaste/caste lower than hers. The ritual husband might have casual or regular sexual relationships with his ritual wife, if both parties were willing. A woman was free to receive casual visitors of appropriate subcaste/caste and accept a small cash gift at each visit. But a more regular visitor had certain customary obligations, which included the offering of various gifts during festivals. When a woman became pregnant, it was essential for one or more men of appropriate subcaste/caste to acknowledge probable paternity by providing a fee to the midwife. If no such man would do so, she would be either expelled from her lineage and caste or even killed by her matrilineal kinsmen. The child born out of such union could not be accepted as a member of his/her lineage and caste. The biological fatherhood of a child was often uncertain. It was presumed to lie with the man or among the men who had paid the delivery fee. Even when it was known with certainty, the genitor had no economic, social or ritual obligations to or rights in the child. The guardianship and care of all children were vested entirely in the matrilineal kinsmen of the property-owning unit to which their mother belonged.

22. The Nayar case has been cited by anthropologists in order to argue both against and for the use of legal paternity as a universal criterion of marriage. Leach<sup>30</sup> points out that a Nayar child uses a

<sup>30</sup> E. R. Leach, "Polyandry, inheritance and the definition of marriage", in J. R. Goody, ed., *Kinship* (Baltimore, Maryland, 1971), pp. 153-154; originally published in *Man*, vol. 55

term of address meaning "lord" or "leader" towards all its mother's lovers, but the use of this term does not carry with it any connotation of paternity, either legal or biological. Hence, according to him, the notion of fatherhood is lacking among the Nayar, although certain elements of a normal marriage institution are present. He does not think it possible to find a universal definition of marriage, but the institutions commonly classed as marriage are concerned with the allocation of a number of distinguishable classes of rights.

23. Gough, an anthropologist well-known for her investigations among the Nayar, disagrees with Leach and regards the Nayar unions as marriage mainly because the concept of legally established paternity was of fundamental significance in establishing a child as a member of his lineage and subcaste/caste. She thinks that for purposes of cross-cultural comparison a single, parsimonious definition is necessary and suggests the following: "Marriage is a relationship between a woman and one or more other persons, which provides that a child born to the woman under circumstances not prohibited by the rules of the relationship, is accorded full birth-status rights common to normal members of his society or social stratum."<sup>31</sup>

24. One implication of Gough's definition is that in any society each person having "full birth-status rights" is the child of a relationship which can be called marriage. But there are societies in which such rights accrue to persons born of relationships which are not recognized as marriage according to prevailing legal or customary rules.<sup>32</sup> If Gough intends to give some special legal significance to the term "full" in "full birth-status rights", her implications may be valid for most societies. But in Caribbean and some other societies the children born out of casual visiting unions which are not recognized as marriage from legal or customary points of view do have full social recognition.

25. Several types of union can be distinguished in these societies, depending mainly upon the stability,

(1955), pp. 185-186. Leach provides a few examples of types of rights which marriage may serve in different societies, including the following: (a) to establish the legal father of a woman's children or the legal mother of a man's children; (b) to give husband/wife right in the spouse's sexuality; (c) to give husband/wife partial or monopolistic right over spouse's labor services or property. None of these rights, according to Leach, is invariably established by marriage in every known society. Perhaps in a similar vein, the *Multilingual Demographic Dictionary* refers to marriages as unions between "persons of opposite sexes which involve rights and obligations fixed by law and custom", p. 31.

<sup>31</sup> K. Gough, "The Nayars and the definition of marriage", *loc. cit.*, pp. 374-375.

<sup>32</sup> Gloria A. Marshall, "Comparative analysis", in David Sills, ed., *International Encyclopedia of Social Sciences*, vol. X, p. 10. The author also points out that operating with Gough's definition, no investigator could classify as married any particular woman who had not borne children. So she suggests that if marriage is defined as "the *jurally valid and socially (or publicly) recognized* assumption of kinship roles of husband and wife", there would be few or no problems concerning the distinction between marriage and its socially recognized alternatives. But this definition appears tautological.

living arrangement of the partners and customary/legal recognition of the union. The most commonly used terms for the three main types of union, particularly in the relevant literature for Caribbean societies, are: (a) visiting; (b) common-law; and (c) legal.<sup>33</sup> The legal union is sometimes referred to simply as "marriage" and common-law union is sometimes referred to as "common-law marriage". The terms "consensual" or "customary" are often used with the same implications as "common-law".<sup>34</sup>

26. Although monogamy is the form of marriage practised by most couples in almost all societies of the world, a cross-cultural discussion of marriage and family should include two other forms of marriage, namely polygyny and polyandry, which are often linked under the single term "polygamy". Even when polygyny or polyandry is permissible or approved in a society, it cannot be practised by a large proportion of men and women due to the following reasons, among others: (a) a large disparity in sex-ratio is rare; (b) a large number of marriageable men or women may have to remain unmarried or celibate and may become a source of social disorganization.

27. The task of categorizing a society as monogamous, polygynous or polyandrous is beset with several problems. Two of them are: a discrepancy between ideal/approved/permissible and actual practice; and the difficulty in setting up quantitative criteria concerning the incidence and intensity of polygyny and polyandry.<sup>35</sup>

<sup>33</sup> See, for example, G. W. Roberts and L. Braithwaite, "Fertility differentials by family type in Trinidad", *Annals of the New York Academy of Sciences*, vol. 84, No. 61 (1960), pp. 963-980; G. T. M. Cummins, H. G. Lovel and K. L. Standard, "Population control in Barbados", *American Journal of Public Health*, vol. 55 (1965); Judith Blake, *Family structure in Jamaica* (Glencoe, Illinois, The Free Press, 1961), pp. 249-250; Henri Léridon, "Les facteurs de la fécondité en Martinique", *Population* (France), vol. 26 (1971), pp. 277-299; Moni Nag, "Patterns of mating behaviour, emigration and contraceptives as factors affecting human fertility in Barbados", *Social and Economic Studies* (Jamaica, West Indies), vol. 20, No. 2 (1971), pp. 111-133; which appeared in Spanish as "Comportamiento conyugal, migración y anti-concepción que afectan a la fecundidad humana en Barbados", in *Conferencia Regional Latinoamericana de Población*, Proceedings of the Conference held at Mexico City, August 1970 (México, 1972), vol. 1, pp. 379-386. In the same volume, see Walter Mertens, "Investigación sobre la fecundidad y la planificación familiar en América Latina", pp. 200-202.

<sup>34</sup> See, for example, *Multilingual Demographic Dictionary*, p. 9; Robert Winch, *loc. cit.*, p. 2; Centro Latinoamericano de Demografía, "Reunión de trabajo sobre evaluación de programas de planificación familiar" (Santiago, Chile, 1970), p. 7.

<sup>35</sup> In an attempt to study the relationship between polygyny and fertility, Nag categorized a society as high on the scale of the incidence of polygyny if 20 per cent or a higher proportion of all married women were polygynously married at the time of investigation. Murdock also used the 20 per cent limit for differentiating the degrees of incidence of polygyny, but it is not clear whether he meant the same thing. See G. P. Murdock, "World ethnographic sample", *American Anthropologist*, vol. 59 (1957), p. 670; Moni Nag, *Factors Affecting Human Fertility in Nonindustrial Societies: A Cross-Cultural Study*, Yale University Publications in Anthropology, No. 66 (New Haven, Conn., Yale University Press, 1962), pp. 93-94.

28. There are individual and group variations in the ages at which women and men attain their capacity to reproduce, but these variations are much less limited in range compared with those in the norms and averages of age at marriage of women and men in human societies. These norms and averages are related to a multitude of socio-cultural variations and there are evidences of considerable changes in the same society over a period of time.

29. The difficulties involved in the definition of marriage, stated above, apply equally to the definition of age at marriage. In some societies, for example, in India, a girl and a boy may go through a marriage ceremony much before their puberty, but the girl may continue to live in her parental home without having any sexual relations with her husband until she reaches puberty. On the other hand, in a Caribbean society, a young couple may begin having a sexual relationship and also children at an early age, but may not go through the marriage ceremony until much later. For the sake of brevity and simplicity, the following discussion is confined to age at first marriage only and mainly to monogamous societies which have sanctions against reproduction prior to a formally recognized marriage.

30. Probably marriage and kinship are fields in which anthropologists have contributed their best, but age at marriage is one of the topics they have talked about least. This gap may be because of the following characteristic features, among others, of the societies they have primarily studied so far: (a) difficulty in the determination of age; (b) recognition of marriage as a gradual process rather than as an event recognized formally; (c) generally early marriage of women, around the period they attain menarche. If the age at marriage of women is found to be delayed considerably in a society, anthropologists have sometimes discussed it.<sup>36</sup>

#### Variations in space and time

31. There are very few countries in the contemporary world that have adequate data for calculating directly the average age of women and men at marriage. It can, however, be estimated from the census data concerning marital status by age groups. One such measure devised by Hajnal<sup>37</sup> is known as "singulate

<sup>36</sup> For example, among the people of Tikopia, a small island in the British Solomon Islands, marriage for both men and women is regarded as an honorable state, but they "tend to marry rather late, that is, in their early or middle twenties". Raymond Firth, "Family in Tikopia", in M. F. Nimkoff, ed., *Comparative Family Systems* (Boston, Mass., Houghton Mifflin, 1965), p. 107. In the study of an Irish village, one of the earliest studies of a peasant community by anthropologists, the authors discuss the socio-economic factors leading to delayed marriage and non-marriage among them. See C. M. Arensberg and S. T. Kimball, *Family and Community in Ireland* (Cambridge, Mass., Harvard University Press, 1940), chaps. 6-8.

<sup>37</sup> John Hajnal, "Age at marriage and proportions marrying", *Population Studies* (United Kingdom), vol. 7 (1953), pp. 111-136.

mean age at marriage". Dixon<sup>38</sup> has found reasonably good data for 57 countries in their respective censuses undertaken around 1960, from which she has computed this measure. The singulate mean ages at marriage for the five regions in which she groups these countries are presented below in summary form:

Region	Number of societies in region	Mean age at marriage	
		Women	Men
Middle East .....	11	19.6	24.9
Asia .....	14	20.9	25.1
Eastern Europe .....	8	21.6	25.1
English-speaking overseas .....	4	21.4	24.6
Western Europe .....	20	23.2	26.2

SOURCE: Ruth B. Dixon, "Explaining cross-cultural variations in age at marriage and proportions never marrying", *Population Studies* (United Kingdom), vol. 25, No. 2 (1971), pp. 215-233.

32. It is obvious from this table that around 1960 the western European region had the highest average age at marriage for both women and men. Individual country variation is naturally much greater than regional variation. For example, the singulate mean age of women at marriage is 16.8 years for India and 25.5 years for Ireland, and the corresponding figures for men are 21.8 and 28.5, respectively. The means for men are higher in all countries, with an age gap ranging from two years in Yugoslavia to nine years in the Libyan Arab Republic. The gaps are larger in Asia and the Middle East than in other regions.

33. Recent studies in historical demography have demonstrated that there were considerable changes in the age gaps between grooms and brides in a few European countries. In Colyton, grooms and brides were of the same average age in the sixteenth century; there then followed a period when brides were normally older than their grooms and then came a period when grooms were normally older than their brides.<sup>39</sup>

34. Although Hajnal gave some evidence of a "non-European" pattern of early and universal marriage in western Europe of the Middle Ages, other evidences indicate a high average age at marriage and a high proportion of non-married women in parts of Europe at least as early as the sixteenth century and perhaps even in the fourteenth century.<sup>40</sup> In recent years, however,

<sup>38</sup> Ruth B. Dixon, "Explaining cross-cultural variations in age at marriage and proportions never marrying", *Population Studies* (United Kingdom), vol. 25, No. 2 (1971), pp. 216-218. India and Ireland represent the two extremes among the 57 countries analysed by Dixon.

<sup>39</sup> E. A. Wrigley, *Population and History* (New York, McGraw-Hill, 1969), p. 105.

<sup>40</sup> J. Hajnal, "European marriage patterns in perspective", in D. V. Glass and D. E. C. Eversley, eds., *Population in History: Essays in Historical Demography* (London, 1965), pp. 101-143; E. A. Wrigley, *op. cit.*, p. 90. The present paper does not deal with the quantity of marriage or non-marriage because of lack of space. It is, however, correlated highly with the age at marriage (R. B. Dixon, *loc. cit.*) except for some societies in which religion, such as Catholicism or Buddhism,

there is a trend among couples in many European countries and in the English-speaking countries overseas towards earlier marriage and a trend among some non-European countries towards delayed marriage.<sup>41</sup>

#### Socio-cultural correlates

35. There are evidences from recent studies in historical demography of a few European societies to support Coale's contention that the control of age at marriage and proportions marrying was the clearest response to changing economic conditions before and during the early stages of demographic transition in these societies. But this control was found to diminish as the availability and efficiency of contraception methods increased.<sup>42</sup> The importance of economic indicators is also demonstrated in explaining the variation in the singulate mean age at marriage in contemporary countries. But it is truer for western countries than others. The youths in wealthier western countries have been marrying earlier, particularly since the end of the Second World War, as the financial constraints on early marriages are being lessened. The most important factor, however, in explaining the variability in singulate mean age at marriage of women is that it is generally higher in societies with a higher proportion of literate teen-age girls.<sup>43</sup>

36. The early age at marriage in the traditional Asian agrarian societies is related to the characteristic features of their social structure, religious beliefs and value systems. The ideal of patrilocal extended families and the importance of corporate patrilineal kin-groups, such as lineage and clans, have been considered two such important features.<sup>44</sup> The dependence of the newly married couple on these kinship institutions minimizes the necessity of their economic self-sufficiency prior to marriage in many western societies, even in the pre-industrial period. The custom of impartible inheritance (e.g., primogeniture or ultimogeniture) and the notion of independence of the nuclear family in many pre-industrial agrarian societies have contributed to delayed marriage among them.<sup>45</sup> It is, however, extremely difficult to validate these associations by statistical tests.

37. According to Hindu religious beliefs, only a son can perform certain of the religious rites after the death

encourages persons to remain non-married for the whole or part of their life.

<sup>45</sup> Kingsley Davis and Judith Blake, *loc. cit.*, p. 217.

of his father. The father is doomed to a particular kind of hell unless these rites are performed. The word for son in Sanskrit is *putra*, which literally means one who saves from *put*, the hell.<sup>46</sup> This belief still holds for many contemporary Hindus and encourages early marriage for men since a son can be begotten only through marriage.

38. In kinship-oriented societies, marriage is usually arranged by older kin who are eager to marry off their girls quite early for the following reasons, among others: (a) early marriage assures maximization of procreation and helps to remove the stigma of barrenness; (b) younger girls are sexually more attractive and, therefore, bring a higher bride price or need a lower dowry; (c) loss of virginity or pre-marital pregnancy on the part of an unmarried girl may bring disgrace upon the family and the whole descent group, or may be considered sinful; (d) marrying off children may be a religious duty, and a source of honour and prestige on the part of the parents; (e) addition of a daughter-in-law to the family may be viewed as an economic advantage, since her services replace those of daughters who leave in marriage.<sup>47</sup> Davis-Blake, however, thinks that there is no empirical evidence to demonstrate that parental control over the selection of marital partners has been primarily associated with very early marriage. She presents some interesting reasons and illustrations to support her view that "social changes that release parents from intense moral obligation to marry off their children will allow the older generation to use its control to prevent early marriage despite favourable conditions encouraging it."<sup>48</sup> But it is difficult to identify such social changes which will make the parents want to marry off their children at a delayed age, as well as allow them to retain their control over it, except for a very short transitional phase of socio-economic development.

39. Age at marriage is related to the welfare of women, from both the physical and the social points of view. The consensus of medical opinion is that the chances of miscarriage or still birth increase with increasing age of women at marriage.<sup>49</sup> But there are evidences to support the view that these chances are quite high in pregnancies occurring at a very early age, and that at a later age, the reproductive organs of a woman who has had a miscarriage or still birth at an early age are likely to be damaged. As a consequence, she may become relatively infecund.<sup>50</sup>

40. The social advantage of a delayed age at marriage of women is often pointed out in terms of the time this delay allows them to develop their own abilities and shape their own ambitions. It may make them more selective with respect to whom they wish to marry, thus leading to a more satisfactory life, whether married or not.<sup>51</sup> Many early marriages in western societies result from pre-marital conceptions. Prësser<sup>52</sup> points out that the postponement of early motherhood and hence of early marriage in these societies could lead to greater marital stability and greater diversity of life-styles for women. The United Nations has declared that child marriage and betrothal of young girls before puberty should be prohibited. The range of legal minimum ages for the marriage of women lies between 12 and 20 years across countries, while actual averages are somewhat higher. Dixon<sup>53</sup> has shown that in most countries the average age at first marriage of women tends to be higher among educated and employed women and higher in urban than rural areas.

#### *Age at marriage and fertility*

41. If contraceptives and other birth-control methods are used widely and effectively in a society, the age at marriage is not expected to have any direct significant effect on its fertility level. Undoubtedly, however, it is one of the most important among the 11 "intermediate" variables identified by Davis and Blake,<sup>54</sup> through which, and only through which, fertility level can be affected, particularly in a non-contraceptive situation. Unfortunately, neither the fertility data nor the data regarding age at marriage are available for a sufficient number of non-contraceptive societies so that a satisfactory statistical analysis can be made to determine the significance of their association. A cross-cultural study<sup>55</sup> of 48 non-industrial societies, which were rated as "high" and "low" in terms of some quantitative criteria concerning fertility level and age

<sup>54</sup> Kingsley Davis and Judith Blake, 1956, *loc. cit.*

<sup>55</sup> Moni Nag, *Factors Affecting Human Fertility in Non-industrial Societies*, pp. 194-195.

at marriage, did not reveal any negative association between them. Another study<sup>56</sup> relating the degree of early marriage (represented by the percentage of married women aged 15-19 years) with the unweighted average gross reproduction rates indicates, however, such a negative association.

42. The absence of such an association in the former study may be due to the fact that the societies that were rated "high" did not have a sufficiently late average age at marriage to have a significant negative effect on their fertility levels.<sup>57</sup> This assumption is supported by the same data on rural Ireland for 1911, which show that the fertility levels of the two groups of women married at ages under 20 years and at ages between 20-24 years differ very little, but the difference of the former group compared with others married at ages 25-29 and 30-34 years was quite significant.<sup>58</sup> Ireland provides a classical example of the reduction of fertility due to a very late age of women and men at marriage and to non-marriage of a considerable proportion of women and men.<sup>59</sup> The dynamics of Irish fertility and marital patterns are related to various socio-cultural factors, such as Catholic values concerning extramarital relationships, means of subsistence and rules of inheritance.

43. There are a few other convincing evidences of a negative association between age at marriage and fertility. For example, the historical demographic study of Crulai (France) for the period 1674-1742 shows that the mean number of children per completed family was approximately 8, 6 and 4 for women who married on the average at 20, 25 and 30 years, respectively.<sup>60</sup> A 1930 study<sup>61</sup> of women in the United States of America

showed that roughly something of the order of one half of the reproductive deficiency of the women below the postulated ideal performance disappeared when corrections were made for the effect of deferred marriages upon mean parities. It was also found that even in 1930 the effect of contraception in reducing the fertility of the United States women was less than the effect of the delayed marriage. The recent trends towards later age at marriage among women in the United States was less than the effect of the delayed marriage. This recent trend towards later age at marriage occurred after a long-term downward trend since the 1890s and particularly during the 1940s and 1950s. The recent trend in the decline of birth rates in the United States can, perhaps, be explained mainly in terms of widespread and effective use of contraceptives, abortion and surgical sterilization, but the recent trend towards later marriage cannot be ruled out as an associated factor.<sup>62</sup> Some studies<sup>63</sup> done in Latin America indicate that the effect of the decrease in fertility due to increased age at marriage may be offset by higher fertility levels among the older cohorts. Some studies<sup>64</sup> in Latin America suggest that a significant proportion of urban-rural fertility differentials observed there may be due to delayed marriage in the cities. The importance of a decrease in the number of married women aged 15-19 in the reduction of Argentine fertility has been pointed out by Rothman and de Janvry.<sup>65</sup>

44. Several studies concerning the association between age at marriage and fertility have been conducted in India.<sup>66</sup> One survey conducted in the 1950s showed that the completed fertility of women marrying between 14 and 17 years was 5.9, while that of women marrying between 18 and 21 years was only 4.7.<sup>67</sup> Another study in an urban community found that, with reference to fertility, there is an optimum age at marriage for women. In Mysore it has been shown that a rise in the age of women at marriage from under 15 years to 16-18 years would produce a rise in fertility, but postponement of marriage to 19-21 years or beyond would produce an appreciable decline in fertility.<sup>68</sup> Agarwala

<sup>56</sup> *Measures, Policies and Programmes Affecting Fertility, with Particular Reference to National Family Planning Programmes*, Population Studies, No. 51, (United Nations publication, Sales No. E.72.XIII.2), p. 50.

<sup>57</sup> The average age at marriage was regarded as "high" if it was estimated as 18 years and over, and "low" if it was less than 18 years. See Moni Nag, *Factors Affecting Human Fertility in Nonindustrial Societies*, pp. 89-90.

<sup>58</sup> The average number of live births for women married at under 20, 20-24, 25-29 and 30-34 years were 8.81, 8.04, 6.79 and 5.57, respectively. See D. V. Glass and E. Grebenik, "The trend and pattern of fertility in Great Britain", *Papers of the Royal Commission on Population* (London, 1954), vol. 6, part 1, p. 271.

<sup>59</sup> Frank Lorimer, *op. cit.*, pp. 171-176; K. H. Connell, "Land and population in Ireland: 1780-1845", in D. V. Glass and D. E. C. Eversley, eds., *Population in History: Essays in Historical Demography* (London, E. Arnold and Co., 1965), p. 428.

<sup>60</sup> Louis Henry, "The population of France in the eighteenth century", in D. V. Glass and D. E. C. Eversley, *op. cit.*, pp. 434-456. See also Etienne Gautier and Louis Henry, *La Population de Crulai, Pavoisse Normande* (Paris, 1958). At the same time, the danger of generalizing is signalled by Longone, who points out that before 1750, in completed families in which the wife married at age 20, the mean number of children born was 10.8 at Sainghin, 8.3 at Crulai and 6.6 at Saint-Sernin and Thezels. See P. Longone, "La Démographie historique", *Population et Sociétés* (France), No. 17 (1969), p. 3.

estimated that raising the age at marriage of women in India to 19 would yield a 29.2 per cent decrease in the birth rate over a period of 30 years. Subsequent studies<sup>69</sup> indicate that Agarwala over-estimated the negative effects of a rise in the age at marriage.<sup>70</sup> But in spite of disagreements concerning the extent of reduction, these studies all show that an average age at marriage beyond 20 would definitely reduce the birth rate.

45. During the past two decades, several countries (including India and the Union of Soviet Socialist Republics) have raised the minimum legal age at marriage in the interest of maternal/child welfare and/or a reduction in the rate of population growth.<sup>71</sup> Although the legal measures are not expected to be enforced uniformly in all these countries and are not likely to have any significant effect on their birth rates, at least in the immediate future, these measures are likely to induce some changes in the value system favourable to individual and social welfare.

#### FAMILY DEVELOPMENT

##### *Developmental cycle*

46. A cross-section of the members of any society will inevitably show a broad age distribution; likewise, a profile of its families will reveal many variations of, as well as deviations from, the ideal type, to which homage is paid. One of the purposes of this paper is to dispel the idea of the family as a static entity. Not only do family types differ across societies and within societies, but any one type is characterized by phases of development over time and is subject to variation in the sequence of its phases, dependent upon the socio-cultural and demographic constraints upon its adherents. It is known that a nuclear family composed of two parents and two children, for example, is not the same when the children are toddlers as when they are off at college in a dormitory. Nor does a patrilocal extended family composed of a couple and their married sons with children remain the same when one or both of the senior parents dies and the married children become separate units for purposes of consumption and/or production. Likewise, a monogamous family may become polygynous or polyandrous in societies

<sup>71</sup> *Measures, Policies and Programmes Affecting Fertility*, *loc. cit.*

where plural forms of marriage are permitted. Thus, as one would be loath to make generalizations about groups of individuals without controlling for age, one should refrain from generating statements about family types and associated socio-cultural variables without examining for the effects of the phase in the family cycle.

47. The concept of family-in-process is particularly important for those family observers considering questions of change and the family in flux owing to industrialization and modernization. It is obvious that a distinction must be made between normal "cyclical" change and "secular" change.

48. The concept of the developmental cycle was formulated by Fortes.<sup>72</sup> His concern was with domestic groups. The developmental cycle concept is used here as it applies to changes over time in the size and composition of families, that is, related persons living together, be they in nuclear, extended or other formats. Fortes contends that the domestic group be analysed temporally as well as spatially and sets forth three characteristic phases or stages: the phase of expansion, covering the period from marriage through completed procreation; the phase of dispersion or fission, during which the children are marrying; and the phase of replacement, marked by the death of the parents and the taking over of family property and the social position of the deceased parents by the children. He rightfully maintains that a census of a community that ignores the developmental factor is prone to distortion of reality. He therefore suggests that samples of families representative of the developmental phases always be drawn when characterizing the domestic organization of a society.

49. The Fortes model represents an important contribution in its advocating the processual as opposed to static views of the domestic group. Clearly, several types of households might be found in a society, depending upon the phase of the developmental cycle. The phases themselves are determined not only by social rules, but by such demographic realities as the age-sex composition of the population and by economic conditions which encourage or discourage family formation and expansion.<sup>73</sup> Moreover, there is a correspondence, although by no means an exact equivalence, between the life cycle of the individual and the developmental cycle of the domestic group. Given similar biological limits, such as life span and maturation rates, cross-cultural variations in the timing of family-cycle phases are not entirely arbitrary. Still, for every biological change one cannot pin-point a universal social marker. Not all societies require marriage at puberty,

<sup>72</sup> M. Fortes, "The development cycle in domestic groups", in J. Goody, ed., *Kinship* (London, Cambridge University Press, 1966), pp. 85-98.

<sup>73</sup> Harold A. Gould, "Time-dimension and structural change in an Indian kinship system", in Milton Singer and Bernard S. Cohn, eds., *Structure and Change in Indian Society* (New York, 1968).

for example. If not mutually determinant, however, such biological processes are interrelated.<sup>74</sup>

50. To ensure their very survival through biological and social reproduction, societies have a vested interest in regulating the life cycles of individuals. Public rituals commonly mark the arrival at such phases as puberty, marriage, pregnancy and death. Norms from the domain external to the family determine its fission and fusion processes.<sup>75</sup> Rules of descent, inheritance and post-marital residence patterns very much affect the size and composition of the co-resident family structure. It has been proposed, for instance, that lineal transmission of property from parent to child leads to earlier fission of the production unit than does lateral inheritance from sibling to sibling; the delayed break-up of the latter derives from the fact that brothers expecting to inherit from one another are more likely to remain together. Eurasia is characterized more by lineal inheritance systems, whereas lateral transmission is more frequently found in Africa. The inheritance systems themselves have been linked to agricultural technology, with more advanced areas thought to value lineal transmission, which has the effect of maintaining socio-economic differences.<sup>76</sup> Smaller family groups would be expected where lineal transmission is found, then, as a result of the inheritance norm, itself reinforced by the agricultural system.

51. Where newly married couples establish themselves is also a major determinant of the developmental cycle. If they join the already existing family of origin of the husband or wife, they will not be forming a new family as much as comprising the "extended phase" of the original family. Post-marital residence patterns are usually associated with the prevailing rules of descent and inheritance (e.g., patrilineal, matrilineal) in the society.<sup>77</sup> In some societies, whether or not an adult brings his/her spouse home after marriage depends upon sex and order in the sibling hierarchy. For instance, among the Khasi of Assam (India), the youngest daughter inherits the largest share of property and the ancestral home, and her husband comes to live there when she marries.<sup>78</sup>

52. The families in a society may not follow any particular cycle. For example, in Andros (Bahamas), the comparison of household censuses<sup>79</sup> taken at two points in time failed to reveal a "typical" cycle, even

though adult life histories and a cross-section of the population had suggested that one existed. The investigator found eight possible household types and estimated that the average household would experience five changes in type throughout its life cycle, thus making 40 combinations possible. The data confirmed that the potential variation was in fact approximated much more so than would be expected, were a typical cycle followed. For Black Caribs, likewise, the family cycle is by no means predictable; a woman may experience several visiting unions before proceeding to a consensual or legally married union, if she does so at all; her living arrangements will depend in part upon the cash income available to her and her partner.<sup>80</sup> A recent study in Senegal<sup>81</sup> demonstrates the difficulty of isolating family types where a large proportion of families are "incomplete"; the age of adult males is highly correlated with the type of family in which they reside, and a secular change in the frequency of polygynous unions may be occurring. What emerges from this discussion is the notion of a number of cycles going on in any society, a picture far different from the characterization of whole societies by a single family type or cycle.

#### *Family types*

53. The preceding discussion was intended to discourage easy stereotyping of societies by static family types when, in fact, it is clear that every generalization can be confronted with numerous exceptions. None the less, science calls for generalizations when possible; furthermore, one stands trapped by a literature which, for the sake of generalization, has referred to certain family types in illuminating the evolutionary history of the family, its geographical variations and relevant socio-cultural correlates of those variations. It is, therefore, with hesitation, but out of necessity that, in the pages that follow, such terms as "nuclear family" and "extended family" are used. One should at least think in terms of nuclear family cycle, extended family cycle and so on, and bear in mind that no two families experience the cycle identically. What has been written for the domestic group in this respect is perhaps an apt rationale for generalizations about family type: "A form of the co-resident domestic group can be said to be the familial institution of a society in permanency over time if a sufficient number of persons being born into that society are being continuously socialized within domestic groups of the structure nominated."<sup>82</sup> The relative number of persons at the aggregate level experiencing each family type in a society is necessary for identifying its familial institution. But such data are not available for most of the societies in the contemporary world and would perhaps never be available for the past.

### Variation in family types

54. In order to get a rough idea of the cross-cultural variation of the prevailing family types, there is no better alternative than to depend mainly upon the available ethnographic sources. Murdock<sup>83</sup> has compiled from these sources socio-cultural materials including the "prevailing form of domestic or familial organization" for 412 clusters of societies from different regions of the world. Following the principles laid down by

him concerning adequate representation and other criteria, it has been possible to categorize 286 societies according to their "prevailing form of domestic or familial organization".<sup>84</sup> Their distribution in the six different regions of the world is presented below in tabular form.

<sup>83</sup> P. Murdock, "Ethnographic atlas: a summary", *Ethnology* (United States of America), vol. VI, No. 2 (1967), pp. 109-236.

<sup>84</sup> *Ibid.*, pp. 111-114.

Familial organization	Africa	Circum Mediterranean	East Eurasia	Insular Pacific	North America	South America	Total
Extended	26 (50.0)	16 (40.0)	22 (43.1)	21 (40.4)	28 (62.2)	22 (47.8)	135 (47.2)

SOURCE: Based on principles in G. P. Murdock, "Ethnographic atlas: a summary", *Ethnology* (United States of America), vol. VI, No. 2 (1967), p. 155.

Note: Figures in parentheses represent the percentages of different forms in each region. For the present purpose 10 different forms identified by Murdock have been condensed into six.

55. The table given above illustrates the variation in "prevailing" family types, as well as the diversity within each region. Some of the results, however, would come as a surprise to those whose concept of the socio-cultural unit is identical with that of a country. It would be difficult for most contemporary North Americans to believe that only 6.7 per cent of their societies are characterized by the nuclear family. But this figure would not appear to be erroneous if they were aware that, for the study of human cultural institutions, a socio-cultural unit comprising only, say, 500 people, is equally important as one comprising 200 million people. Moreover, anthropologists describing a society very often do so in terms of "ethnographic present", that is, in terms of the situation existing prior to any significant cultural influence from outside. Despite these supportive arguments, one should be very cautious in taking too seriously the typological distribution in the table for the following reasons, among others: (a) data are compiled only from the societies for which literature is available; (b) not all of these works are written by trained anthropologists; (c) it is very difficult to decide whether the description relates to ideal or actual patterns.

56. It should be remembered that the percentage distribution would be very different from that given above in the table if any of the following alternative

procedures were to be adopted: (a) taking a country as a unit; (b) referring to percentages of residential or interactional types of family existing in a society at a particular point in time (for example, the 1960s); (c) giving differential weights to units according to their respective total population. There would be specific difficulties and limitations with respect to each of these procedures, but they deserve consideration when doing further comparative research on family and kinship.

#### Nuclear family: socio-cultural correlates

57. Early theories to the contrary, the nuclear family does not appear to be associated only with a high level of technology. The social organization of many societies with primitive technology (for example, the Bushmen of Africa and other hunting-gathering peoples for whom the small family is an asset in terms of mobility and distribution of resources) is based on the nuclear family.

58. The nuclear family has existed for centuries in Europe. Evidence has recently appeared which denies the widespread existence in pre-industrial Europe of the "Classical Family of Western Nostalgia", i.e., large patriarchal kin groupings.<sup>85</sup> The social organization

<sup>85</sup> Peter Laslett, *loc. cit.*, p. 8; William J. Goode, "The theory and measurement of family change", in E. H. Sheldon

(Continued on next page)

of feudal mediaeval Europe centred on the nuclear family, and it maintained that urban rather than rural families of pre-industrial Europe were more likely to be extended.<sup>86</sup> Any declines in family size witnessed over the past century can be attributed more to declining fertility than to structural changes.

59. Even if industrialization did not provide its impetus, it is, none the less, maintained that the nuclear family is highly adaptive to modern life, since nuclear families are mobile and provide the emotional fulfilment missing in industrial jobs. On the other hand, the harmful aspects of the mobility provided by the nuclear type of family has been stressed by some authors. Mead<sup>87</sup> points out that the chance of a post-partum depression for a woman in the United States of America is directly proportional to the distance she is from any relative or friend. She states sarcastically that the "form—the Nuclear Family—was not named after the Bomb, . . . but . . . it is just about as dangerous as the Bomb".

60. Four phases have been described for the cycle of the nuclear family in modern industrial societies: (1) the phase of expansion; (2) the phase of dispersion; (3) the phase of independence; and (4) the phase of replacement.<sup>88</sup> The phases are adopted from the Fortes model for the domestic group described earlier, with the addition of the "independence" phase, a period when children have left home, and husband and wife are still alive and active. The phase of independence is important where mortality is low and many parents survive long beyond their children's marriages. Over the past half a century in the United States, with lowered fertility and a reduced age at completion of childbearing, coupled with increased life expectancy, the relative length of these phases has modified considerably. The net result is an increasing phase of independence with its associated social problems, such as providing for the elderly in terms of social life and medical care and creating alternatives for healthy middle-aged women who have outlived their motherhood roles. Furthermore, as is true of all family types, class and ethnic differences in the timing of the phases, as well as in the achievement of the ideal type, have been observed. Members of the higher social classes, for example, are more likely to delay marriage and childbearing in order to pursue advanced education.<sup>89</sup> Non-white families in the United States are less likely

than white families to be nuclear;<sup>90</sup> more households are headed by women, and grandchildren and parents of the heads are present more often than in white families.<sup>91</sup> The same is true for lower-class Negroes in Guyana, where, despite the prevailing ideal of the nuclear family, the inferior social position of males considerably diminishes their status-conferring function in the family and thus in part accounts for the high frequency of woman-headed households.<sup>92</sup>

61. Christianity has been related in several ways to the nuclear family. Whereas the religions of societies where extended familial organization prevails frequently encourage ancestor worship, Christian scripture reads, "Let the dead bury the dead", thereby implying the independence of the generations. Furthermore, the newly wed "leaves his father and his mother", thus establishing neolocal residence and the freedom from wider kinship responsibilities which that signifies.<sup>93</sup>

62. It is frequently remarked that conjugal roles are much more intimate in nuclear than in extended families. Where husband and wife have fewer obligations to their original lineages and also fewer expectations from them, this greater emotional dependency would be expected. Husband-wife communication is heightened, and this fact may have significant bearing on decisions regarding reproduction.<sup>94</sup> Equally, if not more important for fertility, the nuclear family has tended to encourage later marriages, as described in the section on age at marriage, than in societies where extended family systems prevail.

#### *Extended family: socio-cultural correlates*

63. For the purposes of this paper, the extended family is defined as any group of related persons living together which includes, but is larger than, the nuclear family of parents and their unmarried offspring. This term is intended to include what is referred to in the literature as collateral and generational "extended" families, "joint" families, "stem" families and "consanguineal" families.<sup>95</sup> Characterizing a society as extended

<sup>90</sup> *Ibid.*, p. 287.

<sup>94</sup> Reuben Hill, "The family and population change", *loc. cit.*, p. 25.

<sup>95</sup> The important debate over distinctions between these types is therefore minimized here, but their value should be recognized inasmuch as intrafamilial and other roles can be expected to vary accordingly. A man's authority in a patrilocal extended family, for instance, will depend in large measure upon whether he and his wife and children are living with his father's family of procreation or with his brother's; his relationship to the head may in turn influence his and his wife's decisions about reproduction. For detailed discussions on the stem family as a type distinguished from the extended family, see Thomas K. Burch, "The size and structure of families: a comparative analysis of census data", *American Sociological Review*, vol. 32, No. 3 (1967), pp. 347-363; and Peter Laslett, *loc. cit.*, pp. 16-21. The consanguineal family, comprised of mother, unmarried daughters and their children, admittedly meets only partially the definitional requirements in that a nuclear family unit may never be present.

and W. E. Moore, eds., *Indicators of Social Change* (New York, Russell Sage Foundation, 1968), p. 321. For an interesting French comparison see Alain Collomp, "Famille nucléaire et famille élargie en Haute-Provence au XVIII<sup>e</sup> siècle (1703-1734)", *Annales* (France), vol. 27 (1972), pp. 969-975. Several other articles and brief reviews in the same volume deal with French studies in historical demography and especially "family reconstitution".

<sup>89</sup> Mervyn Susser and W. Watson, *Sociology in Medicine*, 2nd ed. (London, Oxford University Press, 1971), pp. 280-294.

rests on whether or not a majority of the people can be found in an extended family over significant proportions of their lifetimes.

64. Although the family of interaction is not the focus of this paper, its importance cannot be overlooked, particularly in the case of the extended family. In some cases, the criterion of "living together" may prove artificial since extensive help- and visiting-networks may exist between relatives who are close neighbours of one another.<sup>96</sup> Such broader networks physically outside the nuclear family may also influence its internal functioning; for English couples, conjugal role-segregation has been shown to increase with close-knit as opposed to loose-knit kin networks on the part of the spouses.<sup>97</sup> Families in a nuclear phase, or separated only for purposes of employment, may still abide by the roles and obligations which would be expected of them were they living together; thus it is very common in India for brothers residing apart in nuclear units to contribute towards the education and marriage expenses of each other's children.<sup>98</sup> For young married couples in the United States of America, the financial assistance of parents can be considerable; and it is ironical that this extended kin dependence enables them to maintain themselves at least spatially independent. Still, a stage of "living together" may never occur. A survey<sup>99</sup> in Bogota showed that in the year preceding the survey one third of married women had received assistance from members of their families of orientation. Elsewhere, an investigation of wives attending one of the Family Planning Clinics at Isfahan concluded that "the influence of a mother or a mother-in-law, felt very frequently, can either support or undercut the counsel of a clinician seen by a woman only occasionally".<sup>100</sup>

65. For reasons such as those given above, it has been suggested that the term "extended family household" be distinguished from the "extended family", with the latter meant to cover "all relatives in habitual contact with a person, irrespective of whether they live with him".<sup>101</sup> Since the data limitations currently prevent any generalization beyond "extended family household" composition, one can only acknowledge the importance of the interaction system, while continuing to employ "extended family" as a term implying related persons in co-residence.

<sup>96</sup> Sarma has coined the term "kinship neighbourhoods" to describe this situation. See Jyotirmoyee Sarma, "The nuclearization of joint family households in West Bengal", *Man in India* (India), vol. 44 (1964), pp. 193-206.

<sup>101</sup> Peter Laslett, *loc. cit.*, p. 30.

66. Whether cultural ideals for the large extended family could ever have been actually realized is a subject which has fostered an important debate in the literature. On the one hand, it is claimed that despite wide variations in cultural ideals, in practice, most societies have been characterized by families of similar small size owing to the high mortality and short life expectancies prevailing until recent times.<sup>102</sup> Others argue that sociological mechanisms, such as adoption and other means of incorporation, exist in all societies to ensure that enough kin, fictive as well as genetic, shall be mustered to fulfil functions associated with the variety of cultural ideals.<sup>103</sup> The case of the Japanese provides an example of the latter. When a man has no son to carry on the patriline, he adopts a man who takes on the family name, marries one of his daughters and serves as his heir.<sup>104</sup>

67. The ethnographic literature is replete with such examples of fusion of outside members, but the mere existence of such arrangements tells nothing of the frequency with which they are employed. In a very important test of the hypothesis positing the universal similarity of household size, Burch,<sup>105</sup> using United Nations data on household size, has shown that, in fact, the range across countries is small, with by far the majority of them averaging households of from three to six persons. Still, within this range there is a bi-modal distribution, with the developed countries occupying one peak at from three to four persons per household and the developing countries occupying another peak of about five or more. The author suggests that the higher fertility alone of the developing countries could account for this limited difference and that the large extended families are extremely rare in practice. He later appears partially to contradict the differential fertility hypothesis by comparing the households of several countries by presence of other relatives.<sup>106</sup> Thus, whereas households in India are only twice as large as households in the United States of America, they contain six times as many "other relatives". The point is well taken that despite small differences in size across countries, an analysis of the composition of those differences may be qualitatively very important. Thus, the presence of an adult "other relative" may have a very different meaning for intra-familial interaction than the presence of an additional child of one's own.

68. With reference to household size, Goody<sup>107</sup> notes that variability is limited "in spite of, not because of, variations in fertility and mortality". Thus, instead

<sup>102</sup> Marion J. Levy, Jr., "Aspects of the analysis of family structure", in Ansley J. Coale and others, eds., *Aspects of the Analysis of Family Structure* (Princeton, N.J., Princeton University Press, 1965), pp. 1-63.

<sup>106</sup> *Ibid.*, p. 359.

<sup>107</sup> J. R. Goody, "The evolution of the family", *loc. cit.*, p. 115.

of attributing similarities to demographic determinism, he reasons that cultural mechanisms, such as marriage, adoption and inheritance, serve to limit rather than augment household size. This argument is in line with his general contention that the units of production (the term he prefers rather than family or domestic group) are necessarily small in all societies.

69. A few examples of extended family cycles in different societies are described below. Despite the reasonable claim which might be made that there are as many family cycles as there are families, none the less, certain general cyclical patterns can be identified for broadly defined groups of people.

70. The Indian extended family has perhaps received the most attention. For North India three phases of the developmental cycle have been suggested: (1) replacement of daughters by daughters-in-law; (2) demise of the senior male agnate; (3) severance of male siblings' co-parcenary ties.<sup>108</sup> Within the cycle, several family types could be distinguished: an extended phase in which the parents have died and brothers, with their spouses and offspring, live together and a nuclear phase in which the brothers have split and each lives separately with his wife and children. When their sons, in turn, marry and bring home daughters-in-law, new extended families appear. Extended family dependants are not limited to spouses and offspring; first cousins, nieces and nephews may be also present.<sup>109</sup> The timing of the break-up of the family units differs by region. One author maintains, on the basis of a review of 10 studies, that "most (rural people at least) live in either a joint or a supplemented nuclear family". She defines a family as "joint" only if it includes two or more related married couples and, according to her, "supplemented nuclear family" is "a nuclear family plus one or more unmarried, separated, or widowed relatives of the parents, other than their unmarried children".<sup>110</sup>

71. For the Balkan *zadruga*, the cyclical process is similar. The sons born to a couple may elect to live independently when they marry, but more often they choose to stay at home, whether or not the father is still living. The break-up of brothers occurs as their own families of procreation grow.<sup>111</sup> On Moala Island,

Fiji, the death of a family head signals the dispersion of the grown sons; but the timing of the split depends upon family size. In the case of a large family, the break-up can come soon after the head's death, because there will be enough grown sons to meet subsistence needs. Small families wait until the grandsons of the original head have grown and can contribute to the labour force, before the split occurs. When the head survives beyond the point where he can still visit the produce gardens, he is divested of his authority by one of his sons who takes over and moves into his house; and he, in turn, must retire to a smaller house until he dies.<sup>112</sup>

72. The functions and cultural supports of the extended family have been widely discussed. In the absence of organized social services provided by the larger society, the extended family has served to assure co-operation in labour, insurance against economic misfortune, child care and socialization, social security in old age and so on.<sup>113</sup> Where high mortality results in large numbers of widows and orphans, the extended family system provides a shelter for them.<sup>114</sup> It is supported by value systems and religious beliefs. Filial piety receives particular stress; and in many societies, much rests upon ritual observances in the name of the ancestors and untarnished continuity of the family name. Traditional Japanese custom, for example, maintained that ceremonial acts and respect could help assure the welfare of the ancestors, upon whom the welfare of living family members very much depended.<sup>115</sup>

73. Whereas the nuclear family clearly has a limited life span, it is difficult to say when family formation and family dissolution take place in the extended family. A kind of immortality which emphasizes self-extension is implied in the value systems associated with it, i.e., the survival of the family name.<sup>116</sup> An individual's status is also more likely to be ascribed than achieved where his position depends upon his inheritance and where his living arrangements are, to some extent, predetermined.

74. Certain patterns of intra-familial relations are associated with extended family types. Because spouses come to live with the extended family, the latter has an interest in their qualifications and is usually more

<sup>108</sup> H. A. Gould, *loc. cit.*, p. 417.

Cohn, eds., *Structure and Change in Indian Society* (New York, 1968), pp. 346-347 and 390. By definition used in this paper, "supplemented nuclear family" qualifies as extended family. The author, in fact, lists 11 family types for India (plus an "other" category) which are not to be interpreted as necessary phases in any typical family cycle although, of course, every family cycle represents its own selection from any combination of these types. According to her, "While the majority of people may live in such joint and supplemented nuclear families, the majority of families, defined here as commensal units, are probably nuclear in structure".

involved in the mate-selection than is true of nuclear families.<sup>117</sup> Furthermore, since neolocal residence is not fostered, the sibling bond is often stressed over the conjugal bond. For these reasons, husband-wife communication is generally less intimate. In patrilocal extended families of India, the role of the daughter-in-law is likely to be somewhat difficult. It changes with stages in the developmental cycle, as when the daughter-in-law herself becomes a mother-in-law. Still, throughout the cycle, women are generally subordinated to men and have inferior status in various respects. Likewise, male roles in the extended family change with phases in the cycle; younger men, whose fathers are still alive and heading the household, experience lower status than older men who have inherited family authority positions.<sup>118</sup>

75. Generally speaking, intra-familial relationships tend to be more formalized in extended families, in part because mate-selection is based less on spontaneous love and more on practical considerations, in part because family property is at stake and emotional entanglements could mean disaster, in part because parents should treat their nephews/nieces equally with their children and not prefer one sibling over another and so on.

76. The relationship between class and extended family has been investigated for some societies. Again, it is for India that some of the most detailed literature exists. It has been hypothesized that the upper castes and wealthier groups should have a higher frequency of extended family households than the lower castes and poorer groups.<sup>119</sup> However, one comparison of 26 studies concludes, "At best, there is only a partial correlation between caste rank and proportions of joint families".<sup>120</sup> The greatest difference found existed between the "Untouchables", with a comparatively low proportion of extended families, and all other castes. Land ownership was shown to be even less strongly related to prevalence of the extended family, an interesting finding considering that family ownership of land is often thought to keep brothers together.

77. Admittedly, the relation between caste and extended families is possibly confounded by differential effects of modernization upon the class strata. The *élites* may have traditionally been found in extended families, but their modern business and professional occupations may demand a spatial mobility incompatible with the extended family; the poorer castes may be evidencing continued kin solidarity in the urban industrial setting.<sup>121</sup> But the evidence is contradictory, with some authors claiming that, in fact, the extended family is

strengthened by industrial and entrepreneurial exigencies.

78. The fate of the extended family in the face of industrialization, modernization and Westernization has stimulated fruitful, if inconclusive, discussion. One authority<sup>122</sup> maintains that while "no set of determinate relations among family and economic or technological variables" has been demonstrated, still the process of industrialization does seem to change family patterns away from extended kinship ties and towards the independent nuclear family unit. Others have questioned the incompatibility of the extended family with industrialization, and it appears fair to say that, at least for the transition phase, the extended family may prove very functional. Even for England, it has been claimed that early industrialization brought more complex domestic groups.<sup>123</sup> Recent Venezuelan data show that the number of other relatives 25 years and older in households is higher in urban than in rural areas.<sup>124</sup> In such cases, more extended families might be attributed to migrants to the city temporarily residing with kin, although an analysis in three countries between other relatives per household and migration did not show any significant relationship.<sup>125</sup> Obligations to the extended family can, of course, be viewed as a burden in terms of individual upward mobility, as well as an aid in terms of finding urban housing, obtaining employment and the like.<sup>126</sup>

79. A very good case has been made for the advantages for successful industrialization deriving from extended family organization.<sup>127</sup> A few families of industrial leaders of the city of Madras (India) were studied, with the intention of identifying not only change, but persistence in the extended family system. Structurally, more nuclear than extended families were found; none the less, help-patterns of the extended family system prevailed. Moreover, the extended family was shown to provide capital for investments, an authority-structure suited for decision-making in business, and continuity of management as older family members retired and were replaced by their juniors.<sup>128</sup> The author discusses the adaptive process whereby home and industry are compartmentalized, with the former being regarded as "traditional and religious" and the latter as "modern and secular". Still, he

observes that the supposed congruence of pre-industrial social structure and industrial needs is counteracted by potential mistrust among co-owners of the family business, an inadequate number of males in the family, tax laws discouraging family capital accumulation and so forth. Despite these handicaps, he reports that instances of the ideal could be found.

80. Outside of India, two examples can be cited. The *doozuku*, or extended family of Japan, has declined with industrialization and urbanization, as industrial jobs have lured excess sons away from the farms where, traditionally, they would have stayed with the parental family.<sup>129</sup> Economic changes, which now enable a man to farm alone whereas previously several men were advantageous, have had the effect of shortening the Balkan *zadruga* cycle now that sons can leave home sooner and establish themselves independently. On the other hand, the decreased mortality has fostered lineal extension and, moreover, for sons working near the family house, the cash economy has strengthened the extended family.<sup>130</sup>

81. Urbanization and its related features have an effect on intra-familial behaviour and attitudes. Shared recreation for husbands and wives, such as the cinema, is likely to be more common for urban than rural couples.<sup>131</sup> Among Japanese parents, the desire to live with the married son is more pronounced among farmers than metropolitans.<sup>132</sup> Secular education, particularly for women, also fosters a change in familial attitudes. Educated women in India were shown to be less favourable to extended family living than either rural or uneducated urban women.<sup>133</sup> Educated women are more likely to be older at marriage than their unmarried counterparts and to have minds of their own, which might lead to greater conflict with their mothers-in-law.

82. In sum, the changes in family patterns brought by industrialization and modernization are varied and accompanied by the adaptive persistence of pre-industrial social structures.

#### *Family type and fertility*<sup>134</sup>

83. It has been proposed by a number of social scientists that the extended family system encourages

higher fertility than the nuclear family system. Lorimer states that "the whole cultural context in which extended families tend to be idealized is likely to be conducive to high fertility".<sup>135</sup> According to him, however, societies emphasizing corporate unilineal kin groups, such as clans and lineages, tend to encourage high fertility more than the societies emphasizing extended family. A number of characteristic features, particularly early and universal marriage, which are expected to be conducive to abundant reproduction, have been identified.<sup>136</sup>

84. These propositions stimulated a number of empirical studies, mostly in India. But these studies were conducted with a view to testing the association between family type and fertility, taking families within a society as units, not by taking societies as units. The results obtained in the Indian studies were somewhat unexpected but, more or less, consistent. They showed that, in general, the women living in extended families have lower cumulative fertility than those in nuclear families, although in some cases the difference is very small.<sup>137</sup>

85. Although the above-mentioned empirical studies conducted in India do not help the propositions of Lorimer, Davis and others, they pose an interesting explanatory problem. Nag and Driver suggest that women in extended families have less frequency of sexual intercourse than those in nuclear families owing to lack of privacy and to the kinship pressure for observing the periods of abstinence more strictly in extended families. Another suggested explanation is that if too many children are born to a couple living in an extended family they are more likely to leave it and form a nuclear family than otherwise.<sup>138</sup> This illustrates how fertility may affect family type.

86. Burch and Gendell<sup>139</sup> have shown that for a satisfactory explanation of the observed phenomenon in India and for a better understanding of the relation-

<sup>134</sup> An excellent article reviewing the theoretical propositions and empirical studies on this topic and identifying the conceptual and methodological problems involved in these studies has been recently published. It is proposed to summarize here briefly only the important theories and studies related to the topic. See Thomas K. Burch and Murray Gendell, "Extended family structure and fertility: some conceptual and methodological issues", *Journal of Marriage and the Family* (United States of America), vol. 32, No. 2 (1970), pp. 227-236.

ship between family type and fertility more studies on the following lines are needed: (a) studies based on the aggregate level (taking society as a unit); (b) studies collecting the marital and residential history of women, as well as their reproductive history; (c) studies with more refined concepts of family type than have been done so far; (d) studies taking family as an interactional unit rather than a dwelling unit.

#### DIVORCE AND DEATH: FAMILY DISSOLUTION

87. Socially or legally recognized marriage or union implies an expectation of its stability,<sup>140</sup> but most societies in the world have some institutional provisions for divorce or permanent separation of the couple in circumstances that vary tremendously from one society to another. Divorce is, perhaps, a topic on which conflicts between ideals and reality are most extreme. In France, approximately one marriage in ten ends in divorce.<sup>141</sup> Yet, in an attitude survey conducted by the Institut national d'études démographiques,<sup>142</sup> it was found that only 18 per cent of men and 22 per cent of women felt that divorce among couples with children should be permitted, except in exceptional circumstances.

88. In this paper the term "divorce" is used to include "permanent separation" if the latter is socially recognized, although for religious or other reasons, it may not be legally termed "divorce". It does not include temporary separation due to seasonal migration or other reasons. The dissolution of a marriage through divorce may or may not lead to the dissolution of family. In the case of a family consisting only of a childless couple, it does so; but in a society with extended or polygamous family as the dominant type, divorce between a couple may not result in the dissolution of family, as defined here.<sup>143</sup>

#### *Variation in divorce frequency*

89. Data on marital status collected in sample surveys and censuses often give information concerning

<sup>140</sup> Only one society is known in which public opinion undermines the stability of marital relationships, the traditional Crow Indians of North America. Among them, "Divorce is exceedingly frequent, and a man subjects himself to ridicule if he lives too long with one woman". See G. P. Murdock, "Family stability in non-European cultures", in Morton H. Fried, ed., *Readings in Anthropology* (New York, 1959), p. 224; originally published in *Annals of the American Academy of Political and Social Science*, vol. 272 (1950), pp. 195-201.

<sup>143</sup> "Instability of marriage in the Indonesian context does not automatically mean instability of the family or the so-called 'broken home' in the Western sense. It is customary for the children to follow the mother who usually returns to her parents, thereby continuing being part of a family environment". See Mely G. Tan, "The social and cultural context of family planning in Indonesia", paper prepared for the Fifth Asian Congress of Obstetrics and Gynaecology, Djakarta, 8-15 October 1971 (Djakarta, 1971), p. 14 (mimeographed).

the proportion of divorced women and men at the time of the survey or census, but they provide very little information about the frequency of divorce. These proportions are affected by the rate and rapidity of remarriage of the divorced persons. Hypothetically, if every person getting a divorce remarried on the same day, there would be no person with divorced status in the population.<sup>144</sup> A polygynously married man who divorces one of his wives may never appear as divorced.<sup>145</sup>

90. A satisfactory analysis of the frequency of divorce is possible for those countries for which adequate records of all marriage and divorce registrations are available. There are very few such countries in the modern world, not to speak of the past. Hence, for a cross-cultural analysis of divorce there is no alternative but to use data that are neither very reliable nor comparable.

91. Some quantitative data are available in the ethnographic literature with respect to the extent of divorce, but these data are mostly fragmentary and not directly comparable. Murdock<sup>146</sup> selected 40 "non-European" societies and used the available materials to rate them along a scale of "incidence" and "frequency" of divorce. He found that in 24 of these societies, constituting 60 per cent of the sample, the divorce rate exceeded that of the contemporary United States and hence concluded that "we still remain well within the limits which human experience has shown that societies can tolerate with safety".

92. In a cross-cultural study of non-industrial societies relating divorce and fertility, Nag<sup>147</sup> used some quantitative criteria, although very crude and approximate, to rate the societies as "high" and "low" in the frequency of divorce. Data concerning proportions of ever-married women and men who were divorced at least once were used, whenever available. For some societies, however, the proportions of ever-married women and men who were in a divorced state at a particular time were also used, on the questionable assumption that the average rate of remarriage and the average interval between divorce and remarriage did not vary appreciably among those societies. Those societies were considered "high" on the scale of divorce which had 5 per cent or more of their ever-married women or men in a divorced state at a particular time, or in which 20 per cent or more of their ever-married women or men of all ages were divorced at least once. Out of 61 societies, reasonably good data were available for 45. Twenty-two societies were rated as "high"

<sup>145</sup> J. A. Barnes, "The frequency of divorce", in A. L. Epstein, ed., *The Craft of Social Anthropology* (London, Tavistock Publications, 1967), p. 53.

<sup>146</sup> G. P. Murdock, "Family stability in non-European cultures", *loc. cit.*, pp. 220-222. The author did not provide the criteria used for the rating.

<sup>147</sup> M. Nag, *Factors Affecting Human Fertility in Non-industrial Societies*, *loc. cit.*, pp. 98 and 203.

and 23 as "low", according to the above-mentioned criteria.

93. The non-comparability of the divorce measures applies not only to non-industrial societies, which do not keep any records of marriage and divorce, but to many industrial societies. Even the United States of America is categorized as a "developing country" in this respect.<sup>148</sup> The measures used for comparing the situation at different periods also vary. For example, Campbell used the number of divorces per 1,000 married women for showing the increase in the divorce frequencies in the United States from the 1920s to 1968. It rose from 7.4 during the 1920s to a peak of 11.9 in the 1940s, and after a decline in the 1950s climbed to 10.9 in 1966.<sup>149</sup> By using the number of divorces per 100 marriages as a measure, Blake<sup>150</sup> showed that after a peak rate of 40 in 1946, it averaged 38.5 during 1959-1969. She predicted that it would exceed the 1946 rate in 1970.

94. After pointing out the non-comparability and inadequacy of the measures of divorce frequency used so far, Barnes<sup>151</sup> has suggested collecting data from which the magnitude of divorce frequency at any given marriage duration can be computed by relating the number of divorces in a cohort within an interval to the number of marriage-years experienced by the cohort during that interval. These data, if collected from various societies, would make possible more fruitful comparative studies than have been done heretofore.

#### *Socio-cultural correlates*

95. Whatever worth the ethnographic data on divorce may have for quantitative analysis, they indicate clearly that the frequency of divorce does not depend upon the technological level or economic development of a society. Although various writers have stressed the higher divorce ratios among persons of lower socioeconomic status in modern industrial societies, Kirkpatrick<sup>152</sup> points out that it contains some inconsistencies when men and women are considered separately. There is a higher incidence of divorce among college women in the United States compared with less

<sup>148</sup> Arthur A. Campbell, *loc. cit.*, p. 181. The author states that "although we are able to obtain total number of divorces for all States, only half of the States report divorces in sufficient detail to permit tabulation by important characteristics such as age and duration of marriage".

<sup>149</sup> During 1966-1968, it rose by 16 per cent.

<sup>150</sup> Judith Blake, "Reproductive motivation and population policy", in Edward Pohlman, ed., *Population: A Clash of Prophets* (New York, 1971), p. 316.

<sup>151</sup> J. A. Barnes, *loc. cit.*, pp. 47-61, 91-99. He presents a table comparing the number of divorces per annum per 100 existing marriages at specified marriage durations for the following societies: Fort Jameson Ngoni (Northern Rhodesia), 1955; Australia, 1954; London, 1939. This comparison demonstrates that divorces in two societies may be similar in one respect but different in another. Barnes' findings were later compared with the divorce statistics of a Senegalese group. See Luc Thoré, "Mariage et divorce dans la banlieue de Dakar", *Cahiers d'études africaines* (France), vol. 4 (1964), pp. 527-545.

<sup>152</sup> C. Kirkpatrick, *loc. cit.*, p. 316.

educated women and with men at the same college level:

96. Various features of kinship organization are associated with the frequency of divorce. There seems to be higher frequency of divorce in societies with matrilineal descent compared with those with patrilineal descent. In both types of societies, there is always an intimate bond between mothers and children, particularly when the children are small. Hence, the patrilineal descent groups tend to develop stronger sanctions with respect to divorce so that they do not lose the children affiliated to them by birth. Moreover, matrilineal descent is often associated with matrilineal inheritance and matrilocal residence, which is of help to women in bringing up their own children without remarriage, if necessary. The association between rules of descent and divorce frequency has not been tested statistically, but Lorimer<sup>153</sup> cites a number of illustrations from African societies to support the hypothesis.

97. The societies in which the marital partners are chosen by parents or other kin are likely to have lesser frequency of divorce than those in which the partners themselves choose. Ethnographic reports suggest three reasons for this difference: (1) arranged marriage is very often associated with the payment of "bride price" and dowry, which make divorce difficult in various ways; (2) parents with their greater worldly experience are more likely to make a better judgement than the prospective marital partners who, in most non-industrial cultures, are very young; (3) if there is control by a kin-group in arranging a marriage, it is likely to have control over its dissolution also.<sup>154</sup>

98. It was previously stated that arranged marriage is more customary in societies characterized by extended family compared with those characterized by nuclear family. This may contribute to a higher frequency of divorce in the latter societies. But other reasons have also been suggested for a higher frequency of divorce in societies with a nuclear family orientation. As the marriage in such societies is often based on mutual attraction, the husband-wife relationship is expected to be very close and intensely emotional. Goode<sup>155</sup> thinks that this exclusive emotional dependence between husband and wife, without any recourse to dependency on a larger kin group, may lead to a high divorce rate. But he also points out that in this situation the chances of remarriage are also high because there is no larger kin group to absorb the children or to prevent it.

99. The association between kinship organization and divorce frequency does not always follow the same direction. The importance of extended family or descent group in a society may sometimes be responsible for a higher instability of marriage. Supposed or actual sterility of a wife is, perhaps, more often con-

<sup>153</sup> F. Lorimer, *loc. cit.*, pp. 73-86.

<sup>154</sup> G. P. Murdock, "Family stability in non-European cultures", *loc. cit.*, p. 223.

<sup>155</sup> *The Contemporary American Family, op. cit.*, p. 374.

sidered a reasonable ground for divorce in such societies than in others.<sup>156</sup> The traditional familial unit known as *ie* in Japan provides an example. The *ie* had the major role in the selection of a bride and also decided "whether or not the young bride should be returned to her family because of negligence, poor attitude or failure to provide a son".<sup>157</sup>

100. The weakening of the *ie* in Japan, along with the process of modernization, has resulted in a divorce trend which differs from the general trend in other countries. In the 1960's, about one in ten marriages ended in divorce, which is about one third the rate in 1885. Urbanization in Japan is one of the main factors responsible for the weakening of *ie* and the decrease in frequency of divorce.<sup>158</sup> In general, urbanization is reported to be associated with higher frequency of divorce.<sup>159</sup>

101. Religion is one of the most important cultural factors affecting the frequency of divorce. The Catholic religion forbids divorce on any ground. In some predominantly Catholic countries, divorce is not permitted under any conditions, although the physical separation of the spouses may be authorized in special circumstances. In one or two Catholic countries, only non-Catholics may be allowed to divorce.<sup>160</sup> Hinduism also did not permit divorce under any condition until the Hindu Marriage Act of 1955. But the Hindus of lower castes never followed the religious prohibition on divorce as much as those of the higher castes.<sup>161</sup> Until recently, the Moslem religion allowed the husband to divorce his wife without showing any grounds, but a Moslem wife could divorce her husband only through a judge or through a special provision made in the marriage contract. The actual situation currently prevailing among the Islamic societies is not known.<sup>162</sup> In 1966, it was reported that in the United Arab Republic, efforts were being made by women's organizations and

<sup>156</sup> It is difficult to validate this view statistically. Nag found, however, a statistically significant association between frequency of divorce and extent of sterility in his sample of 30 non-industrial societies. It should be pointed out that one of the main reasons for sterility in many societies is the prevalence of venereal diseases. These diseases spread more easily in societies with high frequency of remarriage and of extramarital sex relations. See M. Nag, *Factors Affecting Human Fertility in Nonindustrial Societies*, *loc. cit.*, pp. 99, 203. Even in a recent survey in the Republic of Korea, 37 per cent of male respondents stated that they would divorce if there were no children, while 45 per cent of females would agree to do so. See Lee-Jay Cho, "Economic and demographic influences on the family in Korea", in Arthur A. Campbell and others, eds., *The Family in Transition*, Fogarty International Center Proceedings No. 3 (Bethesda, Maryland, National Institutes of Health, 1971), p. 148.

<sup>162</sup> *Measures, Policies and Programmes Affecting Fertility*, *loc. cit.*, p. 53.

other groups to amend laws relating to the unilateral right of the husband to divorce without showing any grounds.<sup>163</sup>

102. The question of the rights and status of women in relation to divorce is discussed below. Murdock's<sup>164</sup> cross-cultural study of "non-European" societies reveals "extraordinary equality of the sexes in rights of divorce". He found that in 30 out of 40 such societies there is no difference in the rights of women and men to terminate unsatisfactory marriage. The difficulty of divorce for women, at least in two societies (the Arunta of Australia and the Baganda of Africa) appears to be associated with the low status of women among them. In most of the Western societies, women may have equal rights for divorce, but they face a more disadvantageous economic and social situation than men even with the provision of alimony. Women in these societies who marry and become mothers at an early age experience a higher rate of divorce than others<sup>165</sup> and are also perhaps in a more disadvantageous position than others because of their limited educational level and employment opportunity. In Japan, the weakening of *ie* in urban areas has improved the position of women in the family as concerns divorce, but it is also reported that the women usually make every effort to adjust to their marriage because of the lack of opportunities for them for employment and remarriage.<sup>166</sup> Bose<sup>167</sup> argues that in India the family-planning movement should be a part of the social change providing employment opportunities for women. Otherwise, according to him, it will not be possible to solve adequately the problems of divorce, separation or single living which are likely to arise as a consequence of early termination of childbearing and child-rearing.

103. The welfare of the children involved in a broken marriage is not likely to be affected as much in a nuclear family society compared with an extended family society. In the former societies, children are taken care of by kin other than the parents and do not usually suffer from severe economic and emotional deprivation when their parents get divorced. Reports about the children of divorced parents in the latter societies are not very consistent. Susser and Watson think that for normal development, children of a divorced parent need a substitute for the absent spouse.<sup>168</sup> Kirkpatrick finds evidence that in the United States of America divorce runs in families and children suffering from parental divorce may be involved with delinquency, illegitimacy and unwise marriage. But he also cites evidence that "children from broken homes

<sup>168</sup> M. Susser and W. Watson, *op. cit.*, p. 290.

fared as well or better, according to certain criteria, than children from intact but unhappy homes".<sup>169</sup> According to Mead, the people in the United States still believe that the continuity of the family is fundamental to the well-being of every individual child, but there is clear evidence that frequency of divorce has been increasing. As a remedy for this discrepancy between expectation and actuality, she suggests a new "style of marriage in two steps—individual marriage and marriage for parenthood". With the current knowledge of birth control, "every child born can be a child wanted and prepared for".<sup>170</sup>

#### *Divorce and fertility*

104. Divorce may affect the societal fertility level in several possible ways. The most important of these, at least in non-industrial societies, is probably the reduction or complete absence of coitus for a period of time before and after divorce. This causes a loss of the reproductive period of women, which is associated with the following four variables: (1) frequency of divorce; (2) age of spouses at the time of divorce; (3) frequency of remarriage after divorce; and (4) the length of time between divorce and remarriage. Frequency of divorce has, perhaps, the maximal variability. Furthermore, data concerning it, however poor, are better than those for the other three variables. These data were used by Nag<sup>171</sup> to test the association between divorce and fertility in 45 non-industrial societies. No statistically significant association could be found. There were, however, a few societies in the sample whose fertility levels were negatively affected by a high frequency of divorce.

105. As divorce can affect fertility, fertility can also affect divorce. It has previously been noted that in a number of societies sterility or barrenness of women may be an important cause for divorce. Hill<sup>172</sup> suggests that a change in the customary or legal code from husband-initiated divorce because of sterility to divorce as adjudication of conjugal incompatibility reflects a major alteration in the society's reproductive pattern. The net effect of changes in divorce laws on fertility is difficult to determine because of the lack of knowledge concerning many intervening variables.<sup>173</sup>

106. Development-cycle theory enables one to avoid the tendency to categorize every minor variation in the composition of families by a specific type. It distinguishes real structural changes from temporal or incidental changes which deserve no special recognition. Gould<sup>174</sup> illustrates this distinction by the status of a widowed mother in a Hindu extended family. Until the Hindu Code Bill of 1955, she had no rights of inheritance. She would normally live in the collateral extended family which might have developed from the previously existing generational extended family. But if and when the collateral extended family was partitioned, she might be absorbed into any of her sons' nuclear families. Her presence there would not make it significantly different from other partitioned units from a structural point of view, although the death of her husband was crucial to a structural change in the family.

107. The death of any married person in a family brings about many changes in the life of his or her spouse and children. These changes are likely to be more significant in nuclear family societies than in those where larger kin groups are more prevalent. If the surviving spouse has not remarried, he or she, along with young children, can be absorbed in a larger kin group in the latter societies. Modern industrial societies have made provisions for such exigencies by alternative institutional means, such as the social security system, old-age homes, orphanages and so on. But various factors, including greater longevity, sex-differential with respect to life expectancy and difficulty of remarriage when widowed at a later age, are perhaps responsible for the so-called "old-age problems", particularly emotional insecurity, in these societies. There is evidence to show that the mortality of widows and widowers in the United States of America is much higher than that of its general population.<sup>175</sup> Widows and widowers are also reported to have more psychiatric problems than others, but a study in England<sup>176</sup> shows that although they suffer from such problems with greater frequency and acuteness than others for a short period immediately after their bereavement, they return to normal after a few years.

108. The problems of the children arising out of the death of one parent are also more acute in nuclear family societies. Orphanages cannot provide the needed substitute for their normal development.<sup>177</sup> Delinquency and unwise marriage are reported to be more frequent among them than among the children brought up with both parents.<sup>178</sup> The recent emergence of communes in Western societies perhaps reflects the awareness of these problems.

<sup>177</sup> M. Susser and W. Watson, *op. cit.*, p. 290.

<sup>178</sup> C. Kirkpatrick, *loc. cit.*, p. 313.

109. Possibly in all societies more widowers than widows remarry. Some widowers do not remarry for such reasons as old age, unavailability of suitable mates, problems of intrafamily relationship and public opinion. There is perhaps no religious or customary prohibition on their remarriage in any society. But many societies have such prohibitions concerning the remarriage of widows, which are related to socio-cultural factors as well as to reproduction.

*Socio-cultural correlates of widow remarriage*

110. Davis and Blake<sup>179</sup> think that variations in the custom with respect to remarriage of widows in non-industrial societies can be explained mainly in terms of kinship structure. According to them, societies where the extended family prevails have more restrictions on the remarriage of widows than those where corporate lineage and clan systems prevail. The primary reasons are as follows: (a) in the former societies, remarriage outside the group of her deceased husband's immediate kin might require separation from her children; (b) the greater prevalence of the system of levirate in the latter societies. Although logically valid, it is difficult to find satisfactory empirical evidence to support the hypothesis. Nag<sup>180</sup> has shown that there are societies in Africa, and in other regions, among whom any kin-group larger than family does not function as a corporate unit except, probably, for ceremonial purposes, but among whom remarriage of widows is the usual custom. There are also societies emphasizing extended households among whom remarriage of widows is not only permitted, but encouraged.

111. The system of levirate is widespread in societies with unilineal descent group. This system does not necessarily imply the obligation of the widow to marry her deceased husband's brother. In some societies, it extends to any eligible member of his lineage.<sup>181</sup> The levirate system is also quite prevalent in polygynous societies.<sup>182</sup> But it is sometimes found in societies not

emphasizing unilineal kin group or polygyny, for example, among some Hindu caste groups in Punjab, Rajasthan and Gujarat in India.<sup>183</sup> It is quite possible that the system of levirate is positively associated with the system of bride price, which makes it somewhat obligatory for the widow to continue her contribution to her deceased husband's family in terms of reproduction and economic activity. As a step towards raising the status of women, the United Nations has recommended a ban on the levirate system, but it is not known how many countries have taken any action with regard to it.<sup>184</sup>

112. Of all religions, Hinduism is the only one whose scriptures strictly ban remarriage of widows.<sup>185</sup> These scriptures view marriage as a union of souls of husband and wife who are said to reunite after death. But the interpreters of these scriptures applied this view to the case of widows only, not to the widowers. The ideal of *pativrata* (being devoted to the husband alone), popularized by some interpreters, implies fidelity to the husband not only during the present life, but after his death. This ideal gave rise to the well-known institution of *sati*, or immolation of Hindu widows on their husband's funeral pyres. This institution was probably very rarely practised and was banned by law in 1829.

113. Due to the efforts of Indian social reformers, the remarriage of Hindu widows was legalized in 1856.<sup>186</sup> This legalization, however, had little effect on the upper-caste Hindus who had always observed the restriction on widow remarriage much more strictly than lower-caste Hindus. In a survey conducted in the 1960s, it was found that among some lower castes about 30 per cent of the ever-widowed were remarried, while among a few higher castes of the same region the corresponding figure was only 7 per cent.<sup>187</sup>

114. The same survey showed that among Muslims, 35-37 per cent of the ever-widowed women were

<sup>179</sup> K. Davis and J. Blake, *loc. cit.*, pp. 227-229.

<sup>180</sup> M. Nag, *Factors Affecting Human Fertility in Non-industrial Societies, loc. cit.*, pp. 102, 204-206. E.g., among the Tallensi (Africa), levirate was usual, although 41 out of 61 families were of the extended type. Sometimes even old widows among them were remarried to their grandsons, as a matter of formality. See Meyer Fortes, *The Web of Kinship Among the Tallensi: The Second Part of an Analysis of the Social Structure of a Trans-Volta Tribe* (London, 1949), pp. 64 and 239.

<sup>181</sup> For example, among the Ashanti of Africa and the Kazakhas of Central Asia. See F. Lorimer, *op. cit.*, pp. 71 and 94.

<sup>182</sup> Clignet thinks that in some societies polygyny is at least partially due to levirate. See R. Clignet, "Determinants of African polygyny", in J. Goody, ed., *Kinship* (Baltimore, Maryland, 1971), p. 165. Levirate is also common among polygynous hunting-gathering societies, but they also have sororate system of marriage. See K. Gough, "The origin of the family", *loc. cit.*, p. 299. A recent survey conducted in Ghana showed that the percentage of women in polygynous marriage was less in urban areas than in rural areas. The difference was attributed to the fact that the rural family structure, especially polygyny, permits more absorption of widows. See D. I. Pool, "Conjugal patterns in Ghana", *Canadian Review of Sociology and Anthropology*, vol. 5, No. 1 (1968), pp. 246-247.

<sup>183</sup> M. S. Gore, *loc. cit.*, p. 222.

<sup>184</sup> R. B. Dixon, "Women's rights, family planning and family size", *loc. cit.*, p. 18. See also "Draft Declaration on the Elimination of Discrimination Against Women", draft art. 6; General Assembly resolution 2199 (XXI) of 16 December 1966; International Covenant on Civil and Political Rights, art. 23.

<sup>185</sup> The ban was imposed among high caste Hindus at about 300 B.C. Since about A.D. 1000, even a child widow, whose marriage had not been consummated, was banned from marrying. See V. A. Altekar, *The Position of Women in Hindu Civilisation* (Banares, India, Motilal Bernarsidass, 1956), pp. 152-157.

<sup>186</sup> M. Nag, *Factors Affecting Human Fertility in Nonindustrial Societies, loc. cit.*, p. 102. See also K. M. Kapadia, *Marriage and Family in India*, Bombay University Sociology Series No. 3, (London, Oxford University Press, 1955), pp. 161-162.

<sup>187</sup> S. N. Agarwala, "Widow remarriages in some rural areas of northern India", *Demography* (United States of America), vol. 4 (1967), pp. 126-134. The author felt there was no general trend of increasing remarriage among the upper castes, "despite the fact that those who are bold enough to flout it can escape serious social sanctions against them". Gore attributes another reason for the caste differential: higher castes are usually richer; and there would be difficulties in property management if a widow who already had a son by her first husband married a second time and took the son with her to a different residential unit. See M. S. Gore, *loc. cit.*, p. 220.

remarried. There is no religious restriction on widow remarriage among Muslims. It is interesting to note that all except one of the Prophet Mohammed's wives were widows.<sup>188</sup> Despite the absence of prohibitions against remarriage of widows, however, the proportion of widowers appears to be less than that of widows in Muslim-dominated societies, indicating that the chances of the remarriage of widows are less than those of widowers.<sup>189</sup>

#### *Widow remarriage and fertility*

115. The loss of the reproductive period of women due to widowhood mainly depends upon the following three variables: (1) frequency of remarriage of widows; (2) age interval between the husband's death and remarriage of the widow; and (3) the probability of a woman becoming a widow at different ages. A cross-cultural study of 50 non-industrial societies which were rated as "high" and "low" in the scale of proportion of widows not remarried (on the basis both of quantitative and of qualitative information) did not indicate any negative association between the proportion of widows not remarried and fertility level.<sup>190</sup>

116. The relationship between non-remarriage of widows and fertility has been studied more extensively for India than for any other country, because of the religious and traditional ban on remarriage of widows among Hindus. On the basis of the differences in the child-woman ratios calculated from Indian census data for the period 1901-1941, Davis concluded that the "superiority of Muslim and tribal fertility over the Hindu is due in part to their greater toleration of widow remarriage".<sup>191</sup> A study conducted in 1960 in rural West Bengal<sup>192</sup> of two Muslim groups and one Hindu group showed that the average reproductive period lost per ever-married women due to widowhood was very small in all these three groups, and the variation among the three groups was also insignificant. An analysis of the Indian census data from 1901 to 1951 showed that, on average, a woman lost roughly one child during her reproductive period because of widowhood. It should, however, be mentioned that there was a progressive decrease during this period in the loss of reproductive life because of a gradually decreasing mortality rate.<sup>193</sup>

<sup>188</sup> F. Lorimer, *op. cit.*, p. 186.

<sup>189</sup> For example, a sample survey of Java and Madura (Indonesia) conducted in 1964 showed 2.5 per cent of widowers and 14.9 per cent of widows. See M. G. Tan, *loc. cit.*, p. 14.

<sup>190</sup> M. Nag, *Factors Affecting Human Fertility in Nonindustrial Societies*, *loc. cit.*, pp. 100-101 and 206.

<sup>191</sup> Kingsley Davis, *The Population of India and Pakistan* (Princeton, New Jersey, Princeton University Press, 1951), pp. 80-82.

<sup>192</sup> The average reproductive periods lost per ever-married woman among the Hindus, non-Sheikh, and Sheikh Muslims were respectively 1.3, 1.2 and 1.0. The average age at which the women in each group became widows was an important factor in neutralizing the effect of the difference in the frequency of remarriage. See M. Nag, *Factors Affecting Human Fertility in Nonindustrial Societies*, *loc. cit.*, p. 54.

<sup>193</sup> S. N. Agarwala, "Social and cultural factors affecting fertility in India", *Family Planning News* (India), vol. 4, No. 6 (1963).

In a recent analysis of tribal-nontribal differential fertility in India from census and survey data, it was found that there was no systematic difference between the two categories, as inferred by Davis from child-woman ratios. There was, however, a difference for Madras state in 1961 and this difference can be explained mostly in terms of the difference in frequency of remarriage of widows and the average age at marriage.<sup>194</sup> The results obtained so far are not very conclusive, but they show that the fertility level of the Hindus, particularly of the higher castes, was to some extent negatively affected by the prohibition of widow remarriage. But there is no reason to believe that the relaxation of this prohibition may increase their fertility rate, as the forces of modernization that may stimulate this relaxation are also likely to generate conditions favourable to small family norms.

#### CONCLUDING REMARKS

117. The contribution of the present paper perhaps lies primarily in its attempt to integrate the concepts and data from anthropological, sociological and demographic literature. There is a large body of sociological literature on the family; some of the recent writings relate it to population, in particular to fertility. Anthropologists have always been interested in kinship systems, emphasizing more the larger kin-groups, such as lineage, clan and domestic groups. This difference in emphasis is due in part to the fact that anthropologists have traditionally studied societies in which the functions of the family, especially the nuclear family, are not easily distinguishable from those of the larger kin-groups. The anthropological concept of "development cycle", originally formulated with reference to domestic groups, is not fully applicable to all family types described in this paper. But it has been shown that this concept is useful in identifying the phases and processes through which each family type may go and in avoiding simplistic generalizations concerning interrelationships of socio-cultural factors, family types and fertility.

118. The definitions and functions of marriage and family have so far been based mainly on the concepts and values prevalent in Western societies. This paper gives examples of societies from various parts of the world and having attained various technological levels in order to illustrate the problems involved in formulating cross-culturally valid definitions and functions of marriage and family. It does not, however, claim to provide solutions to these problems, but it draws attention to the need for new concepts, hypotheses and empirical investigations.

119. Family-cycle variables are constrained by biological factors but they are more affected by, and also affect, other socio-cultural factors. In a broad sense, the

<sup>194</sup> Moni Nag, "Tribal-nontribal fertility differentials in India", *Demography India*, vol. 2, No. 1 (1973), pp. 105-117. Madras is the only state in India for which the 1961 census provided the age-group data necessary for calculating the child-woman ratio separately for the "scheduled tribes".

level of technology, means of subsistence, external, political and such other factors should be included in the category of socio-cultural factors, but for the purpose of this paper these have been dealt with only peripherally. The processes of industrialization, urbanization and modernization are known to bring about long-term changes in some family-cycle variables, such as age at marriage. This paper has provided a few illustrations to show that these processes do not readily cause a change in the value systems associated with certain other family cycle variables, such as ideal type of family. It has also been shown that some family cycle variables, such as frequency of divorce, are not linearly associated with level of technology. In analysing the spatial and secular variations in family-cycle variables, it has been found that religious beliefs, kinship system, rules of inheritance and a few other socio-cultural factors are of primary importance with respect to some variables.

120. The only population component considered in this paper is fertility, in part because of its current importance in the population policies formulated by various countries and in part because of its hypothesized associations with various family-cycle variables, such as age at marriage, divorce, widowhood and family type. Although delayed age at marriage, frequent divorce and non-remarriage of widows may lead to some loss of reproductive period of women, the empirical evidence available so far does not indicate any significant negative association of these variables with fertility except in a few special cases. Some studies have been conducted on the relationship between family type and fertility; but they can actually provide very little information other than to question the proposition that the extended family system encourages high fertility. Many more conceptual and methodological refinements are needed to state anything more definitely about the relationship between family-cycle variables and fertility. This remark is applicable equally to the following three other family-cycle variables not adequately dealt with in this paper because of limitation of space: (1) non-marriage (including celibacy); (2) forms of family (monogamy, polygyny and polyandry); (3) types of unions (visiting, common-law and legal).<sup>195</sup>

121. Not only do family types differ across and within societies, but any one type is characterized by

<sup>195</sup> For discussions on polygyny and fertility, see: V. R. For discussion on

phases of development over time and is subject to variation in the sequence of its phases, dependent upon socio-cultural and demographic constraints. The concept of family-in-process is particularly important for those family observers making statements about changing family patterns. A distinction has to be made between cyclical and secular changes and between incidental and structural changes. Obviously, any attempt to quantify such processes at the national level is limited by information gathered in the national census and sample surveys. For example, if household data are collected without regard for the relationship among its members, accurate statements concerning family size and type cannot be generated. A series of cross-sectional data collected over time, particularly those amenable to cohort analysis, is useful for understanding the changes occurring in residential family patterns. But for understanding the changes occurring in interactional family patterns, as well as in socio-cultural and fertility patterns, intensive anthropological studies of small communities have to be undertaken along with sociological surveys.<sup>196</sup>

Roberts, "Some aspects of mating and fertility in the West Indies", *Population Studies* (United Kingdom), vol. 8 (1955), pp. 199-227; and "Fecundidad diferencial por tipo de unión y algunas de sus implicaciones en las Indias Occidentales", *Conferencia Regional Latinoamericana de Población*, Proceedings of the Conference held at Mexico City, August 1970 (Mexico, 1972), vol. 1, p. 364.

<sup>196</sup> Specific research needs have been stated in various sections of this paper. For a more comprehensive discussion of needed research, see I. B. Taeuber, "Continuity, change and transition in population and family: interrelations and priorities in research", *loc. cit.*, pp. 317-342.

## POPULATION AND THE FAMILY: OVERVIEW \*

*Charles F. Westoff\*\**

1. The Symposium on Population and the Family was convened to examine the interrelations between demographic change and the family, with particular emphasis on the "micro" perspective of population processes. The focus is both on the family as it influences demographic processes and on the consequences for the family of population change. The intention of the organizers has been to present the accumulated knowledge of social science on these subjects before the World Population Conference in general, and to provide the Advisory Committee of Experts on the World Population Plan of Action with information on which to base their recommendations, which, in turn, will be presented first to the Population Commission and ultimately to the representatives of Governments at the World Population Conference. This paper, as the word "overview" suggests, is an attempt to distil further this knowledge and to emphasize those issues which have some policy relevance. The primary audience for this paper are viewed as those with a policy rather than with a scientific interest in the subject.

2. Those in the various social science disciplines know all too well how thin and uneven available knowledge is when it comes to translating research into policy terms. This general uneasiness is magnified when one turns to such ill-defined, interdisciplinary fields as the family and population. Everyone acknowledges the importance of the family; statements such as the "family is the basic social institution", "the family is the natural and fundamental group unit of society" are repeatedly and strongly asserted. But statements of what might be called "firm" knowledge in the field evoke a less certain tone. The papers prepared for this Symposium, on which this overview is based, reflect both the amorphous nature of the subject-matter and the uncertainty of many of its generalizations. This point is stressed because it is important to alert non-professional audiences to the fact that much of what commonly passes for knowledge in these fields is based on small-scale studies in one country or another, employing varying definitions, measurements and analytical procedures, or on greatly simplified models of complex situations. An attempt will be made to dis-

tinguish those areas in which knowledge rests on fairly firm or on not-so-firm ground. If it is any consolation, the state of much of the available knowledge about the interrelations of population change with economic, environmental, political or other social factors is not especially better grounded and in many instances is even less firm than what can be said about the effects on the family.

3. Despite the organizers' good intentions, the papers for this Symposium scarcely exhaust the topic, and other background papers and information external to the Conference have been used to supplement them. This is not a point-by-point summary of the papers prepared for the Symposium, although it builds on many of the contributions of most of them. Some topics have hardly been covered at all in the papers for the Symposium—such as urbanization and migration—and these important subjects are excluded from this overview.

### FAMILY STRUCTURE AND CHANGE

4. The family is the organized group of society in which demographic processes occur: marriage; reproduction; mobility; dissolution; and death. Some sociologists focus on descriptions of the family as an originally all-embracing organization which historically performed functions now increasingly performed by other, more specialized agencies. In some sense, the process of modernization itself can be viewed as a transfer of functions from the family to other institutions. Despite these losses of such functions as the economic and educational, despite the decline in family size in the developed world, despite high divorce rates and despite some redistribution of the family's remaining functions to other institutions, the social institution of the family shows few signs of atrophy. Near-universal marriage at fairly early ages continues to be the pattern in most societies; high remarriage rates following dissolution suggest that divorce means disenchantment with a particular partner rather than with marriage. The family is probably the least altered of all the social institutions. As Margaret Mead has quipped: "It is the only institution we have that doesn't have a hope of disappearing."

5. Anthropologists have catalogued a wide variety of family forms around the world and through history. Most comparative research has focused on the nuclear

\* The original text of this paper (E/CONF.60/SYM.II/11) was submitted to the Symposium on Population and the Family, Honolulu, 6-15 August 1973.

\*\* Assistant Director, Office of Population Research, Princeton University, Princeton, New Jersey, United States of America.

or conjugal type—basically the married couple and their children, which is the most prevalent form—and the extended family, which ideally includes several generations in lineal descent, various siblings and other relatives. There are variations on this theme in different cultures. A common belief, with little support from ethnographic evidence, is that the extended type of family is the pre-modern form which features very large households and encourages high fertility, while the nuclear form is the family of modern industrial society with small households and low fertility. If there were some intrinsic, direct sociological connexions between family type and fertility, there might indeed be some policy implications. However, the nuclear family does not appear only at advanced levels of technology. It is observed in some traditional African societies as well as in early European history. It would be difficult to conclude, therefore, that the decline of fertility in the past century and a half could be attributed to changes in family structure. Despite the stereotype that different forms of family vary in size according to cultural ideals, research has revealed little variation in household size in the past because of the demographic constraints imposed by historically similar mortality and fertility. It is plausible to hypothesize that extended kinship systems probably operate to reduce the necessity for economic autonomy prior to marriage and thus encourage early marriage, but there is mixed evidence on whether extended families imply higher marital fertility than nuclear families. Fertility has declined among Western societies with nuclear families and in some Far Eastern societies (Japan, Singapore, Hong Kong and the Malay Peninsula) with more extended families. Yet, high fertility remains unchanged in Java with prevailing nuclear families and among the Bengali with extended families. This is an area where further research is clearly indicated and one where the World Fertility Survey, which is just getting under way, can make a real contribution.

6. Although the connexions between family structure and fertility remain obscure, more light is being shed on some of the effects of demographic change on family structure. In countries that have experienced the transition from high to low fertility, there has, of course, been a corresponding decline in the average size of households and families as well as an increase in the proportion of nuclear families and one-person households and decreases in the proportion of families extended across several generations. Internal migration from rural to urban areas also contributes significantly to this process.

7. One of the papers contributed to this Symposium cast new light on the effect of the demographic transition on family size. If the family is viewed as a population, and its size as the number of persons in the family multiplied by the time they live together, it is evident that the typical family of the developing world today is much larger in terms of person-years lived than its predecessor under conditions of high mortality, but that its "size" is spread out over a much greater average

length of family life. Although the average family in the low mortality-low fertility stage has only half as many children as the family in the transitional stage, this "small family system" is actually somewhat larger than that of families in the initial high mortality-high fertility stage.

8. One of the consequences of increases in parent and child survival is the enormous increase (by a factor of three) in the amount of time parents and their children have available for interaction, a consequence of demographic change that must have great significance for patterns of socialization and different kinds of intra-familial relationships. One of the unique characteristics of low fertility and improved survival is the long period of time (13-14 years on the average) that the parents jointly experience after the children have grown and left home.

9. An outcome of this micro-demographic exercise is an estimate that male heirs are either not born to or do not survive 44 per cent of women under high fertility-high mortality conditions, compared with 21 per cent in populations which have experienced decline in mortality but not in fertility. In societies where such succession is important, such a sharp increase in the likelihood of having a male heir may prevent an adverse reaction to the increased burdens of child care resulting from reduced mortality and continued high fertility.

10. The lack of incentive for restricting family size may also result from the fact that the ratio of consumers (children under 15) to producers (parents and children 15 and older) within the family in person-years terms, unlike the simpler child-parent ratio, is only marginally greater in the demographic transition phase than under conditions of high mortality-high fertility. This micro-demographic perspective contrasts sharply with the usual macro-demographic dependency ratios which show a much greater disadvantage for the population in transition. Both perspectives are right. The explanation lies in the fact that the decline of mortality and resulting high increase in population growth means a sharp increase in the number of families (150 per cent per generation). Thus, although within the family the ratio of consumers to producers does not increase sharply with declining mortality, there is a sharp increase in the proportion of children in the aggregate population as a consequence of high fertility and low mortality. The policy implication is that the pressing problem of national economic development, exacerbated by the high load of dependants in the populations of developing countries, does not have a parallel at the family level except in so far as the force of population increase is reflected in perceptions of increased competition among more families. Nevertheless, both of these measures show striking improvement as a consequence of the decline of fertility.

11. One subject that is not covered in this micro-demographic exercise is the dependency of old age. One of the clearly predictable demographic consequences

of the slowing of population growth is the increase in the proportion of persons classified as "old". The proportion 65 years of age and older increases from around 3 per cent in populations with high fertility to 16 per cent in stationary population at low levels of fertility; sooner or later, this transition is inevitable. In societies that are approaching this demographic state, this transition has been reached slowly along with all of the changes implied by the term "modernization", including changes in the status of aged members of the family. Many developed societies are currently struggling with the manifold problems associated with this increase in the numbers and proportions of old people and their simultaneous alienation from the security of the small nuclear family. Their problems of health, income and social identity are serious indeed and they will inevitably increase in severity.

#### FAMILY FORMATION AND DISSOLUTION

12. Most fertility in the world occurs within marriage, overwhelmingly in monogamous marriages. Polygamous forms exist, but demographic and social constraints minimize their frequency. The most common form of polygamous marriages, polygyny, probably reduces fertility through age differences of spouses, lack of exposure and differences in adherence to periods of post-partum abstinence. There is also the possibility, however, that polygynous marriages may appear less fertile because of a tendency to add another wife if the first wife proves infertile.

13. Age at marriage, on the other hand, is of considerable significance for the amount of fertility that a marriage will produce. It has accordingly created a certain amount of interest in population policy circles.

14. Most students of the subject maintain that changes in age at marriage have a much greater potential impact on the fertility of populations in which contraceptive practice is minimal. Although its influence on fertility is certainly less in contracepting populations because of the greater significance of the length of exposure to the risk of conception in populations which do not practise contraception widely, one should not minimize its importance in the developed world. Recent (1970) research in the United States, for example, reveals a considerable difference in the fertility of women (married 15-19 years), ranging from an average of 4.1 for women married under 18 to an average of 2.6 for women married after 24, with linear gradations between these ages, which are hardly insignificant demographic differences.

15. Age at marriage exerts such a powerful effect on fertility because it reflects the combination of many different influences which operate either independently or which reinforce each other. In any society, the younger the woman is at marriage, the earlier she is exposed to the risk of pregnancy at highly fecundable ages (with the exception of the adolescent sterility of child marriages). Conversely, many marriages occur

earlier than they might otherwise because of pre-marital pregnancy, a process that also selects the most fecundable women. Early marriage and/or early fertility forces many young people to leave school or forces women to stop work, which in turn reduces exposure to interests and activities that may compete with the marriage and maternal role. These influences affect both wanted and unwanted fertility which show a similar negative association with age at marriage. Some women are selected for early marriage who are more interested in the familial career; others who married early, having left school or work earlier than they intended, are channelled in a direction which then becomes their dominant role.

16. The effective use of birth control can lower the age at marriage by making it possible for couples to marry early but postpone childbearing, thus reducing the "costs" of marriage in the sense of permitting the couple to remain in school or permitting the woman to continue to work. Historically, in the developed countries, age at marriage declined by from two to five years, after the diffusion of contraception. There was a very early decline in fertility in Western Europe (prior to the eighteenth century) as a consequence of important decreases in the proportions married and increases in age at marriage. In some European countries, age at marriage for females reached 28, with the result of removing a great amount of highly fecundable exposure.

17. Youthful marriage and very high proportions married is the typical pattern of nuptiality in the developing world today. Some countries in this category, such as Chile, Korea, Sri Lanka and Tunisia, have experienced increases in age at marriage which have evidently resulted in the beginning of declining fertility.

18. One of the advantages of increasing age at marriage in the fertility transition, as one observer suggests, is the speed of its effect. Births are prevented among younger, highly fecund couples rather than among older couples towards the end of their fertility.

19. Changes in age at marriage could have significant effects on growth rates in the developing countries. One calculation places the potential effect at reducing the birth rate from the 45 per 1,000 population typical of developing countries to about 30 per 1,000, if the marital fertility currently prevailing in the developing countries were combined with the nuptiality pattern prevailing in Western Europe in the early years of this century. This is just an illustration of the potential demographic effect of altering age at marriage. Without any change in marital fertility, the number of children per woman is reduced because of a shorter total exposure to the risk of childbearing. Moreover, later marriage increases the age at which childbearing occurs, and increasing the average age at childbearing, even without a decline in the number of children per woman, reduces the rate of growth by increasing the length of generations. Of course, it is highly unlikely that such radical changes in marriage customs could occur with-

out other modernizing forces operating, which in all likelihood would be reducing marital fertility simultaneously. There is little optimism that increases in legal minimum ages of marriage would have important demographic effects, but there is some possible evidence to the contrary, for example, in Tunisia. Again, other trends of social and economic development in these countries have been operating to support such a change.

20. The non-demographic effects of raising age at marriage seem to be consistently positive. There is increased exposure of young adults to non-familial activities, including education, which contributes to economic development. It permits greater opportunities for mobility which may take the form of migration to more attractive labour markets. The avoidance of very early childbearing certainly contributes to the health of mothers and their children. One might even assert that later marriage contributes to the quality of marital and parent-child relationships. There is at least some evidence that the probability of divorce decreases with increasing age at marriage.

21. Knowledge of the connexions between marital dissolution and fertility suffers especially from inadequate data. In general, one infers the obvious: high divorce or widowhood rates will depress fertility through the reduction of the length of exposure to the chance of conception. The magnitude of the effect depends upon the age at the time of dissolution, the probability of remarriage and the length of time between marriages. Dissolution rates vary enormously around the world; divorce rates are apparently higher in societies where parental influence over the choice of partners is minimal. Cross-cultural research evidently does not support the assumption that the frequency of divorce is associated with economic development.

#### WOMEN

22. The status of women is both a determinant and a consequence of reproductive behaviour. Women's health and opportunities for education and employment—in general, their level of participation in the non-familial life of the society—both influence and result from their age at marriage and their fertility.

23. The health of women is linked to reproductive behaviour in various ways. Improved health can mean potentially higher fertility through increased fecundability. The reduction of venereal disease is a case in point. Other diseases, such as malaria, rubella and tuberculosis, affect pregnancy completion. Conversely, fertility can affect health. Maternal mortality is affected by both early and very late childbearing, by short birth intervals and by high fertility, which is especially serious when one considers that one in every seven births occurs to women under 18 and above 35, the ages where risks are greatest. Maternal death rates increase markedly beyond three births. A large fraction of maternal mortality is caused by poorly performed

abortions, which are, of course, a symptom of unwanted fertility. The significance of maternal mortality must, naturally, be evaluated in terms of its impact on the whole family.

24. The education of women is an especially critical factor in reproductive behaviour. One study of factors affecting age at marriage in different countries reveals the widespread importance of literacy among teen-age girls. Illiteracy rates are much higher among women than men in most countries, although the situation is evidently changing. Early marriage and childbearing interfere not only with the woman's participation in higher education but, perhaps more critically, in secondary education. The woman who avoids childbearing until her early twenties is more likely to develop interests alternative to maternal roles, is more likely to learn family planning techniques and to be more motivated to use them, is more likely to participate in the economy for longer periods and is more likely to produce fewer and healthier children. Studies of the connexions between education of women and fertility around the world show fairly consistent negative associations, although the "fertility effects" appear at higher levels of education in developed countries. These effects operate demographically both through delays in marriage and through desired family size and increased, effective fertility regulation.

25. Similar generalizations can be offered about the connexions between female employment and fertility, but they are more complicated because type of employment is important. Employment in cottage industry or in agriculture in the immediate vicinity of the home, which is common in many developing countries, does not have the same incompatibility with domestic and maternal roles that paid, full-time employment away from the home in urban, industrial sectors connotes. Such employment is very limited in developing countries for obvious reasons connected with educational and economic development. Thus, the clearest indication of the depressing effects of female employment on fertility appears in industrialized countries.

26. One difficulty in interpreting this relationship is the recurrent question of whether women who have fewer children work or whether women have fewer children in order to work. No doubt both processes operate: women who may have fewer children for whatever reasons are freer to take employment; and women who wish to work may deliberately defer marriage or childbearing in order to permit working.

27. There are many societies in which traditional roles of motherhood are highly rewarded and where the woman's prestige is associated with high fertility, especially the production of sons. It has been reported by family planning clinics in several African countries that women are often more interested in learning how to increase rather than decrease their fertility. In other Western societies, the deferral of marriage and low fertility, perhaps even childlessness among some segments, have occurred as the result of complex historical

trends. In some of these societies, the status of women has emerged, or re-emerged, as an important movement and ideology. As the technology of fertility control has improved and its diffusion has extended, the incidence of unplanned and unwanted fertility has diminished to the extent that some have raised questions about the future of the family. Although one can visualize further losses of function for the family as reproduction and perhaps the socialization of children become less demanding and perhaps increasingly performed by other specialized agencies (day-care centres, for example), it does not seem likely that the family is on the verge of disappearing. As one student of the subject has phrased it: "... fertility decline indicates a rejection of parenthood, not the family".

28. In view of the potential importance of the status of women not only for demographic matters, but for many other aspects of social change, it appears striking that only a few of the economic development plans in developing countries include any reference to the disadvantaged status of women.

#### CHILDREN

29. Although woman's lot is closely linked to reproductive experience, it is the child who is in some ultimate sense the benefactor or victim of conditions beyond its control. High fertility has been shown repeatedly to be associated with high foetal, infant and child mortality. Each of the components of high fertility exacts its toll. Foetal death rates increase markedly at higher maternal ages; infant mortality is pronounced at the younger ages, under 20 and especially under 18. Short intervals between births also play a direct role in child health through their implications for foetal, infant and child mortality. Lastly, high parity itself increases the risks of abortion, stillbirth and infant mortality. Over and above the direct medical connexions, there are the obvious adverse implications for child health of the strain on family resources as family size increases (offset to some extent by surviving children's subsequent contributions to family income).

30. These effects are observed in both developed and developing countries. In the United States of America, for example, the postponement of the occurrence of first births until the mother was in her early twenties would have a pronounced effect on infant mortality.

31. In a very real sense, children are the main subject of this Symposium. One of the prevailing theories in the field is that birth rates will decline when parents in the developing world realize that they no longer have to reproduce at such high levels in order to ensure surviving children who provide status and support in old age. Some limited support for this proposition exists at both the micro- and macro-levels. The most persuasive evidence shows higher fertility connected with the direct experience or fear of child mortality rather than in the correlations between de-

clining infant mortality and crude birth rates which are interpretable on various grounds. The evidence is not overwhelming, but the potential significance of the relationship is certainly important enough to warrant more definitive research on the question.

32. The connexions between fertility and mortality are the easily measurable ones, but they hardly exhaust the subject. There are undoubtedly less measurable dimensions of child health and development that are related to fertility and to the constellations of factors associated with large family size—low income, high density, poor sanitary conditions, malnutrition, poor medical care and limited maternal care, to name a few. Studies have linked family size to various kinds of diseases, with physical growth, with intellectual development and educational opportunity, with behaviour and psychological characteristics. It is difficult, of course, to distil the pure effects of family size from the social and economic *milieux* with which it is so intricately connected. Once again, it must be concluded that child health will be improved by the interrelated processes of social and economic and demographic development. The general relation of health and fertility can certainly be utilized in family planning programmes. It is evident that the health of mothers and of children is a powerful incentive to women and the combination of pre-natal, maternal and child care in clinics with family planning services can be potentially much more effective than such services in isolation.

#### SOME NEW RESEARCH DIRECTIONS

33. There are several new directions of research in areas focusing on the family and population. One of those organized at the East-West Population Institute at Honolulu is an ambitious series of cross-cultural surveys in five Asian countries attempting to measure directly the value of children to parents. The research is intended to test hypotheses about the connexions between fertility and the perceived "costs and benefits" of children.

34. A conceptually related, though professionally distinct, line of inquiry is reflected in its most recent developments by a group of economists at the National Bureau of Economic Research in New York. These efforts are producing a micro-economic theory of family decision-making in which the family or household is regarded as a small firm producing things from which it derives satisfaction. Children are thus viewed as consumer goods which yield services or "utility". The demand for children is determined by the relationship between the perceived gratification of children and the amount of investment required for a given level of quality (e.g., the costs of education) which are in turn related to age of parents, income etc. There are many conceptual problems involved in these attempts to apply the powerful apparatus of economic theory developed for different purposes. Moreover, solid empirical evidence in support of hypotheses derived from this

theory has not yet been forthcoming. Nevertheless, it represents the emergence of an imaginative and potentially rewarding direction of research.

35. One of the most ambitious current research efforts is the World Fertility Survey (WFS), supported by the United Nations Fund for Population Activities and the United States Agency for International Development, and administered by the International Statistical Institute. The WFS is planning sample surveys of households and interviews with women of reproductive age in order to obtain a wide variety of information about the family and reproduction in from 40 to 50 countries, with special emphasis on countries for which even rudimentary data do not yet exist. Although the WFS hopes to produce information on many different aspects of fertility, the subjects currently being proposed will permit testing numerous hypotheses about fertility and the structure of the family, age at marriage, employment of women, marital dissolution and many other characteristics of the couple. This type of research is scarcely new; what makes it noteworthy is the promise of obtaining comparable data on so many relevant subjects from so many different cultures.

36. There are other, quite different frontiers of research that may prove of radical importance for the family and population developments which can only be mentioned in passing. These include biomedical research in genetics and reproduction which may yield technology of great relevance to fertility. One such area, which some believe will become a reality in the next few decades, is the pre-determination of the sex of offspring. It seems clear that the use of such technology would operate to reduce fertility, the extent depending, of course, upon the cultural significance attached to preferences for the different sexes. Such a development could have great potential not only for fertility, but for the sex ratio and related patterns of behaviour and for intra-familial interactions. In the United States, for example, some recent research indicates that if women's preferences for the sex of their children prevailed, the proportion of families with the first-born a male and the second a female would more than double; that fertility would be slightly lower; but that the population sex ratio would only be temporarily made more masculine. Research on this subject in other countries is currently the focus of a group of scholars in a committee of the International Union for the Scientific Study of Population.

37. The improvement of fertility-control technology—methods that are more effective, more acceptable and more easily diffusable—is obviously a potentially important development for the family and fertility. Although methods currently available are certainly capable of reducing fertility if used, these methods have their disadvantages and there is the further likelihood that improved technology might attract couples with low motivation to control fertility.

38. Lastly, there are exciting new developments in genetics and reproductive biology, some of which have

science-fiction qualities portending new forms of reproduction quite different from man's experience. Mankind may indeed be on the threshold of scientific developments with great though hardly immediate implications for the family through the increasing specialization of the reproductive institution. Demographic trends, the reduction of mortality and fertility, carry uncertain implications for the heterogeneity of gene pools which is still another area of research beginning to unfold.

## CONCLUSIONS

39. Some provocative generalizations about the connexions between population growth and the family have been offered which seem an appropriate way to conclude this overview.<sup>1</sup> Bernard Berelson sees two trends of major historic importance: the trend from the large to the small family that has accompanied the whole process of modernization, a trend that is still unfolding in much of the world; and a trend towards viewing reproduction increasingly in terms of the welfare of the child, a trend that Berelson asserts is barely visible. Rydér argues that a convincing case can be made that economic development has typically required assertion of the primacy of the individual over the family, and that this was the most essential basis for modern fertility regulation. Society intervened on behalf of the individual to tip the balance of power: the worker against the owner, the woman against the man, the child against the parent. In the West—and this is a Western point of view—"societies slowly but inexorably took the side of the child against the parent, specifically enforcing compulsory education—delaying more and more the entry of the child into the labour force, and establishing the claim of the child as worker over the fruits of his labour". He maintains that the "core of the solution of the problem of fertility regulation is implementation of a declaration of the rights of children. This is indeed revolutionary; what is required is a reversal of the entire temporal direction of obligation from what the child owes the parent to what the parent owes the child."

40. It has been clear from this Symposium and from the findings of countless studies of history and the contemporary world that the decline of fertility is deeply imbedded in the processes of social and economic development. Indeed, some have insisted that the reduction of fertility will only follow the modernization of the whole society, a process that could be self-defeating given the time factors involved. But it may be that the evidence on this question is not really so clear. Irene Taeuber appears to have the most appropriate formulation, that this is more an area for research rather than a field of knowledge.

<sup>1</sup> See annex for sources of these generalizations and of other ideas and propositions in this paper.

## ON THE IMPACT OF SOCIO-ECONOMIC AND CULTURAL FACTORS ON FAMILY DEVELOPMENT \*

I. Y. Matyukha \*\*

1. The family is a primary cell in society, reflecting all major socio-economic interrelationships in society. While the family may be regarded as an elementary unit, it is a highly complicated phenomenon, which integrates biological, socio-economic, moral, ideological and psychological relations.

2. The family in the Union of Soviet Socialist Republics is the object of study by various researchers, such as ethnographers, statisticians, and psychologists, as well as by experts in law, and in the pedagogical and medical sciences. The most general laws of family development are thoroughly studied by social sciences.

3. Economic and demographic researchers in the Soviet Union consider the family to be a group of members of a household who are related through kinship and common properties, as well as through common income and budget outlays. Thus, the family may be identified as a means of organizing family life and private consumption. The family helps to shape moral and physical properties and obligations towards society. Man's role in society, his social and occupational activities and his ability to bring up children depend considerably upon the level of well-being of the family and upon its moral and social pattern, which, as a matter of fact has a crucial significance for society as a whole and for its progress and development.

4. Being a phenomenon of public life, the family is subject to incessant changes and developments caused by a number of socio-economic factors. The social status of the family, as well as family relations, is predetermined by the kind of existing relations of production. In the socialist-planned economy consistent efforts are being made with the aim of stabilizing the family as a unit of society. One of the major targets of the Soviet State is to secure the prosperity of the family, in the interest both of society and of family members. This approach is based on sound legal and socio-economic measures. The basic Act passed recently concerning marriage and family status stresses the necessity of further family consolidation based on a new kind of communist relations. This Act is a significant contribution to the development of conjugal

relations on a strictly voluntary basis, proceeding from the assumption of a friendly disposition, respect and mutual affection between husband and wife, and a complete lack of any mercantile claims (as proclaimed in Article 1, "Principles of Law concerning Marriage and Family in the Union of Soviet Socialist Republics and in the Union Republics").

5. The family, as a unit of social life, is in the first instance identified by its size and structure, while changes at certain points in time testify to family development. According to the data solicited through the All-Union census of population of 1970, there were 58 million families in the Soviet Union in the reference period. There were 14 million single persons, including those living apart from their families, as well as those not sharing family budgets.

6. The average family size was 3.7 in 1970 as compared with 4.1 in 1939. While the average size of urban families has undergone no significant change in the period from 1940 to 1970, averaging 3.5, rural families have somewhat decreased from 4.3 in 1939 to 4.0 in 1970. This decrease in family size in rural areas may be attributed mainly to rural/urban migration caused by certain developments in agriculture which took place during this period throughout the Soviet Union. Rapid industrial advances were facilitated by the wider use of mechanized operations in agriculture, as well as by the higher productivity of agricultural labour.

7. By modern definition, the family is today identified as the family nucleus, consisting of a married couple and one or two children, that is, the size of the modern family depends primarily upon the number of children. This concept may be best illustrated by means of the data given below, solicited during a sample survey. Survey items covered, among other things, those concerning family structure. The starting-point was to determine the number of children in families both of urban and rural residents.

8. Table 1 shows that nearly half of the sample families had one child, while 35 per cent of the families had two children. Collective farm families markedly exceed the number of urban families with three children and above. As far as smaller families, those comprising one or two children, are concerned, the reverse is true, namely, the percentage of such families among workers and employees is larger than among collective farmers.

\* The original text of this paper was submitted as a Conference room paper to the Symposium on Population and the Family, Honolulu, 6-15 August 1973.

\*\* Candidate of Economic Science, Central Statistical Board, Council of Ministers of USSR, Moscow.

TABLE I. FAMILY DISTRIBUTION ACCORDING TO NUMBER OF CHILDREN AGED UP TO 17  
(Percentages)

Type of family	Families with children aged up to 17	Families with				
		One child	Two children	Three children	Four children	Five children and more
Total families of USSR	100	48.1	34.8	10.0	3.8	3.3
Families of workers and employees	100	50.9	35.5	8.6	2.9	2.1
Families of collective farmers	100	26.3	31.5	16.2	7.7	8.3

9. Family size reduction is an extremely intricate phenomenon. Among the major factors causing family size reduction, disintegration plays an important rôle, primarily through newly formed young couples departing from the family. Family disintegration is in most cases attributed to the changing household and economic pattern of the family.

10. Considering the rural population in the USSR, which has undergone the most significant of changes, it is expedient to note that a peasant family was the model for the agricultural production unit before the Great October Revolution of 1917, as well as in the first years of the Soviet State prior to the collectivization which was successfully implemented in the 1930s, and before the subsequent rapid industrial development in the Soviet Union. A closer look at pre-revolutionary agriculture would show that a conservative stable pattern of a large peasant family, consisting of three or four married couples, was widespread. The size of such a family in some cases totalled from 15 to 20 persons.

11. This conservative type of patriarchal family was necessitated by the mode of agricultural production prevailing at that time, based on private property, on means of production and on inherent labour co-operation in peasant households. This kind of organization was of paramount economic importance for the family. In the pre-revolutionary period, there were more than 20 million small peasant households in Russia, including poverty-stricken households amounting to 65 per cent of the total number.

12. The economic functions of the patriarchal household determined a predominant right of the ownership of the means of production, which accrued to the head of the household. This right considerably blocked the way to disintegration of households and families.

13. The emergence of new relations of production caused by the development of production, the means of production being now in a collective ownership, was accompanied by the voluntary co-operation of peasant households, which took place soon after the Revolution of 1917. A basis was created thereby for a socialist transformation of agriculture. There are currently some 33,000 collective farms and 15,500 State collective

farms in the Soviet Union. With the emergence of large socialist agricultural enterprises, the traditional kind of peasant household is losing its former significance as a production unit and is being transformed into a socio-economic unit. It may happen that personal subsidiary plots, currently owned by the rural population, will reduce and completely cease to exist with the development of socialist agriculture in the Soviet Union. In this case, households in the countryside will be converted into socio-economic groups of persons calling for better management of consumption. This function is now typical for the majority of urban families of workers and employees. The features of this family are the lack of any interdependence of family members caused by private property relations, and the existence of equal rights of male and female members of family, of mutual respect, of collective discussion of all major problems and of sound human attitudes.

14. It is worth mentioning that family disintegration, which is a gradual transformation of the patriarchal family into the so-called democratic family, is a process which is now going on in a number of industrially developed, as well as developing, countries. Some Western experts in social sciences are evidently correct in assuming that family disintegration has become a general tendency.

15. The democratic family is defined as a family where the scope of influence has been primarily subdivided according to an accepted decision concerning the division of labour. Administration is thus subdivided into two nearly equal shares. This kind of family is based on mutual respect and affection, leaving no place for fear and force.

16. One should bear in mind, however, that the actual democratic transformation of the family, which will have no hierarchy whatsoever, is realistic only if it is based on a stable socio-economic status, as well as on a real position of equal rights of man and woman in society.

17. Sound housing and the provision of the population with housing facilities are important factors in family disintegration. The urgent need to have a proper house cannot be overstated, because it is an element of the material culture of society, as well as a factor in happy family life and family development. Housing and its quality clearly indicate the level of life.

18. Housing conditions have always exerted considerable effect on demographic processes in society, on family development, on household activities, recreation and medical care. Planning of housing, in its turn, is in strong interdependence with demographic processes, especially concerning any regularities of family development.

19. A tremendous housing construction project is under way in the Soviet Union. During the period of Soviet Power, more than 2.6 thousand million m<sup>2</sup> of surface area were brought into occupancy in the Soviet Union. The total urban housing inventory has increased fourfold, as compared with 1940, and was about 1.7 thousand million m<sup>2</sup> at the end of 1972.

20. The period from 1961 to 1972 saw the highest housing construction rates, which enabled 132 million persons, or more than half the population of the country, to improve their living conditions or to have their own dwellings built. As a result of this, more than 100 million people enjoyed house-warmings.<sup>1</sup>

21. The Five-Year Development Plan of the USSR envisages a total volume of housing construction of 580 million m<sup>2</sup> in the five years from 1971 to 1975. The average dwelling space per urban inhabitant, which was 11 m<sup>2</sup> in 1970, will increase up to 11.9 m<sup>2</sup> in 1975.

22. Both urban and rural residents in the Soviet Union enjoy various privileges as concerns housing expenditures. Total outlays for rent and utilities (water supply, sewerage, central heating, electricity, gas supply etc.), on average, do not exceed 4 per cent of the total expenditures. Before the Revolution, rent alone accounted for 20 per cent or more of the total outlay of the family budget of working people.

23. Housing problems in the USSR would have been solved long ago had there been no devastating damages inflicted by the Nazi invaders during the Second World War, which destroyed 1,710 towns and settlements and left 25 million people homeless in the areas temporarily occupied by the Nazis.

24. Changes in a family's size and structure are closely interrelated with its well-being and with the right and actual possibility of all able-bodied family members to be gainfully employed. Of great importance also is the provision of old-age pensions guaranteed by the State. Well-being in the Soviet Union is based not on private ownership of the means of production, with the related pattern of distribution and inadequate relations of production, but on incomes produced by people actively engaged in the socialist production processes.

25. The continuous improvement of the well-being of the people of the USSR is an objective economic law of the socialist society. This law finds its implementation in the growth of national income, which is used for further development of production and for the improvement of well-being. The national income of the

Soviet people increased 51 times by 1972, as compared with the pre-revolutionary period and it totalled 315.3 thousand million roubles. For more recent periods, say for the 12 years from 1961 to 1972, an even more evident increase took place equal to an increase of 2.2 times.

26. In a socialist society, increases in national wealth are actually reflected in the improvement of the well-being of each family. Having this in view, about three fourths of the national income is used for consumption, that is, for the meeting of the personal requirements of the population, while one fourth is spent for the expansion of the country's productive capacity with the objective of raising the level of living of the population.

27. In the Soviet Union, radical changes have taken place in the structure of the population according to the means of subsistence, which is testified to by the data acquired through population surveys.

28. As is seen from table 2, persons having employment account for nearly half of the total population of the USSR. Those employed include workers and employees of state, co-operative and public organizations, as well as collective farmers employed in agricultural production.

29. In the Soviet Union, there are no unemployed persons. Every citizen of the Soviet Union has a right to guaranteed work. The right to work is ensured by the Constitution of the Union of Soviet Socialist Republics. The right of every citizen of socialist society, together with his duty, to work is one of the basic foundations of socialism.

30. A successful solution to the unemployment problem in the Soviet Union paved the way for a further increase in well-being. Real incomes of workers have increased 8.5 times in 1972 as compared with 1913, while real incomes of peasants have increased 12 times during the same period. Even for a more recent time-span, the same trend is evident: real *per capita* incomes have increased, 1972 as against 1940, 4.3 times.<sup>2</sup>

31. The main source of the livelihood of workers and employees is wages and salary, while a guaranteed payment, both of cash and in kind, is used as remuneration for the labour of collective farmers. Apart from individual wages and salaries, considerable sums are spent from social consumption funds in the form of various allowances and grants. This should be borne in mind when considering the distribution of national income. From these funds, the population is provided with free education and training to improve professional skill, free medical care, allowances for temporary disability, pensions, scholarships for students, paid annual leaves, free and reduced-price accommodation in sanatoriums and holiday homes, maintenance of kindergartens and day nurseries, as well as a number of other allowances and grants.

TABLE 2. DISTRIBUTION OF THE POPULATION OF THE USSR  
ACCORDING TO MEANS OF SUBSISTENCE

	1959		1970	
	Population (millions)	Share (percentage)	Population (millions)	Share (percentage)
Total population .....	208.8	100.0	241.4	100.0
Gainfully employed .....	99.1	47.5	115.2	47.7
Members of families of collective farmers, workers and employees engaged in personal subsidiary plots .....	9.9	4.7	1.8	0.8
Persons in receipt of State assistance (pensioners and others) .....	12.4	6.0	32.7 <sup>a</sup>	13.5
Fellowship holders .....	1.7	0.8	3.5	1.5
Dependents of individual persons ...	85.4	40.9	87.9	36.4
Self-supporting persons having suffi- cient means for their subsistence ...	0.3	0.1	0.3	0.1

SOURCE: *Vestnik Statistiki*, No. 3 (1973), pp. 82-86.

<sup>a</sup> As of the beginning of 1970, the total number of pensioners had reached 40.1 million persons. Only those were defined as pensioners, during population surveys, whose main source of subsistence was a pension. Those pensioners employed full-time were recorded as gainfully employed. In early 1973, the total number of pension-holders was estimated to be 43 million persons.

32. In 1972, there was an increase in social consumption funds which topped 72 thousand million roubles. *Per capita* consumption was estimated to be 300 roubles, including allowances and grants; average consumption from these funds per average family was over 1,100 roubles per annum. Currently, disbursements from social funds cover almost one fourth of the total aggregate family income.

33. Social consumption funds serve best to indicate the level of living inherent in socialist society. This additional and significant source of income plays an increasing role in family incomes, which may be clearly seen from the data obtained through family budget surveys, as shown in table 3.

34. Family development and changes in the structure of families are greatly influenced by the role women play in society. The Great October Revolution of 1917 swept away all traces of women's inequality and, without exception, has freed women from exploitation and oppression. Extremely striking were the

developments after the Revolution which took place in the eastern regions of the country and completely transformed women's role in local society. The women of the eastern peoples were all, with rare exceptions, illiterate and entirely dependent upon their men, although women's labour played a big role in the economies of these peoples.

35. One of the first decrees issued after the Revolution established equal rights for women and put an end to all kinds of women's inequality with men. As V. I. Lenin put it, during a short period of two years, Soviet Power, established in one of the most backward regions of Europe, has accomplished as much in providing women equal rights with their "strong half" as all advanced, progressive, "democratic" republics in the world have hesitantly managed to have achieved during a 130-year span of time.

36. Women in the Soviet Union have equal rights with men as concerns pay, professional skill and education. Equal rights of women and men are not merely

proclaimed by law, but are correspondingly implemented through a number of socio-economic measures providing for emancipation and equality, as laid down by law.

37. Women in the Soviet Union successfully occupy very important posts in all branches of the economy of the Soviet Union, in science and culture. In 1971, women accounted for 51 per cent of total employment, amounting to 47.3 million persons, as compared with 2.8 million women employed in the economy in 1928, or 24 per cent of the total manpower of that time.

38. Women play an important role in public health and education, which favourably influences health and educational projects, because of women's unique ability to combine high skill and professional experience with female charm and incessant efforts to protect and better raise children, as well as to care for other people's health.

39. Women currently employed as manual and non-manual workers in industry account for 48 per cent of the total manpower; in agriculture, for 45 per cent; in trade and public catering, for 76 per cent; in science and related services, for 48 per cent; and in general management, for 62 per cent of the total number employed. All male and female workers are equally paid in the Soviet Union for the same quantity and quality of work.

40. In the pre-revolutionary period, 55 per cent of all women employees worked as servants of the capitalists, landowners and managers, 25 per cent of the women employed worked as farm hands on landowners' and *kulaks'* estates, thus leaving only 13 per cent of employed women for industry and construction and a mere 4 per cent for education and health.

41. The employment status of women, to a certain degree, has an impact on their role in family life, where women bear the main share of household duties, to say nothing of their specific functions as mothers. Needless to say, an employed woman is rather limited in her time to raise children and to perform household duties.

42. The existing contradiction between a woman's employment and her family and household duties in the Soviet Union is being gradually eliminated by means of the following:

(a) A broader network of pre-school facilities, including kindergartens and nurseries; schools providing for children's stay after classes and their meals, as well as home-assignment-preparation after class; and specialized boarding-schools. Mention should be made also of non-school related children's facilities: children's camps, club-houses and the like;

(b) A rational distribution of household duties among all family members;

(c) A wider usage of home-oriented appliances, such as refrigerators, laundry-machines, cleaners and polishers;

(d) A broader system of public catering, trading centres, especially those with canned goods, as well as

other foods obtained in prepared form; various services could be added to the list.

43. The solution of these problems, along with the full implementation of equal legal rights of women and men in all branches of social life, enable women successfully to combine occupational activities in social production with household duties.

44. An extremely short historical period saw the transformation of a backward country into a universally literate State. The Constitution of the Soviet Union provides women with guaranteed legal rights to education. The All-Union Census of Population of 1970 testified to complete female literacy, as compared with 32 per cent of literate women in 1920. In Tsarist Russia, literacy covered about 8.3 per cent of the total number of women. The level of literacy in the country was almost four times lower than that of urban areas. Women inhabitants of the northern areas, Central Asia and other "border" territories of Tsarist Russia were, but for rare exceptions, illiterate.

45. The share of women with higher and intermediate specialized education is currently increasing more rapidly than that of men, while among employed women, the number with higher or intermediate specialized education is practically equal to that of males. This fact is clearly illustrated by the census data given in table 4.

TABLE 4. UNION OF SOVIET SOCIALIST REPUBLICS:  
EDUCATIONAL ATTAINMENT OF MEN AND WOMEN

Year	Educational attainment per 1,000 persons (men or women)			
	Higher and intermediate specialized education		Persons with higher education	
	Men	Women	Men	Women
Total population aged 10 and over				
1939	127	90	11	5
1970	522	452	48	37
1972	547	478	53	41
Employed persons				
1939	136	104	16	9
1970	654	651	68	62
1972	698	697	78	71

46. The number of women with higher education had, by 1970, increased 8.2 times, as compared with 1939; while for women with intermediate specialized education, an increase of 5.1 times for the same period took place. The increase of men with higher education in 1970 compared with 1939 was 4.8 times, while for men with intermediate specialized education it equaled 4.3 times. As the census data indicate, the number of women with higher or intermediate specialized education has increased, in 1970 as compared with 1939, in the Turkmen Soviet Socialist Republic nine times, in the Uzbek Soviet Socialist Republic 10 times, in the Kirghiz Soviet Socialist Republic 12 times, and in the Tadzhik Soviet Socialist Republic 15 times. Suffice it

to say that the corresponding rate of increase for the entire Soviet Union for the same period was five times.<sup>3</sup>

47. Approximately 390,000 women in the Soviet Union are engaged in scientific work, including 3,500 women with academic degrees of doctor of science and 68,000 with academic degrees of candidate of science. Of the total number of scientific workers, about 2,000 women have the academic rank of academician, active member or corresponding member of the Academy or professor.

48. Radical changes in the social status of women in socialist society have raised women to top positions in the State. In Tsarist Russia, women were deprived of election rights. Today, women not only fully enjoy equal voting rights with men, but are themselves elected to hold various government posts. In 1972, there were 463 women deputies in the Supreme Soviet of the USSR, comprising 31 per cent of the total number of deputies, and 36 per cent of the total in the Supreme Soviets of the Union Republics were women. More than 992,000 women are deputies of local Soviets.

49. One of major family functions is its raising of children. Women play a leading role in performing this function, which is naturally predetermined by their status as mother and by their social status in society. In the Soviet Union, mothers are treated with esteem and respect and are cared for by the State. Women who are engaged in social production are provided with annual paid leave. Additional fully paid maternity leave is provided for periods up to four months following childbirth. A wide network exists of mother and child care designed to provide all possible protection of the mother's health. Medical care in the Soviet Union, being free, naturally covers all women in the country.

50. The Soviet State pays great attention to family maintenance and the rearing of children by a wide-range system of grants and allowances. In 1971, more than 3 million mothers received monthly state allowances for children. Nearly 400,000 mothers with two children were given one-time grants following the birth of the third child. Of great significance in this respect is the introduction of a system of state allowances for families with relatively low levels of *per capita* income. This project is to be implemented in accordance with the Five-Year Plan of Development of the National Economy of the USSR for 1971-1975.

51. Children's pre-school establishments—kindergartens and nurseries—are of paramount importance for children's care and upbringing. In 1971, nearly 10 million children were covered by these establishments; taken together with seasonal pre-school camps and other camps, the number increased, covering about 15 million children.

52. Almost 440 roubles are spent annually on keeping one child in nursery, with parents paying only

18 per cent of this sum. With kindergartens, the figures are, correspondingly, 400 roubles annually per child, with 26 per cent paid by the parents. The remainder is covered from social consumption funds.

53. Worth mentioning is a new educational approach implemented in pre-school children's establishments, according to which a closer link is provided with the subsequent school teaching. Children are taught many subjects related to practical everyday activities, which enable them to have a deeper insight into life and to create new relations with their parents, among the family and with the school and the like. These new relations and attitudes help to enrich a child's outlook and generate new moral perceptions, contributing, thereafter, to more responsible decision-making, useful for both individual and social needs.

54. Family size and family structure are directly influenced by birth rate, which is, in turn, affected by a series of socio-economic factors partially considered above. In this connexion, it should be mentioned that the socio-economic impact on birth rate was duly considered in a Soviet paper prepared for the Symposium on Population and Development, held at Cairo, 4-14 June 1973, "The interrelationships between development and population in the developing countries",<sup>4</sup> related to problems of population and development.

55. The total population in the Soviet Union, in early 1973, was 248.6 million, including 115 million men and 133.6 million women. As is well known, this country experienced heavy losses during two world wars, having lost over 20 million in the Second World War alone. The Soviet Union, nevertheless, has retained a rather stable population increase.

56. During the period from 1926 to 1972, the crude birth-rate in the Soviet Union decreased from 44.0 to 17.9 per 1,000. This birth-rate decline was caused by a number of socio-economic factors. A sample survey was conducted in the USSR in 1969, with the aim of better knowing public opinion on the optimal and expected number of children in a family. As was disclosed during the survey, the overwhelming majority of women queried on that point (more than 80 per cent) were strongly in favour of having an "ideal" family of from two to three children. This is, however, an average for the entire country. An average "ideal" number of children desired in a family may change from one area to another. Thus, in the Ukrainian Soviet Socialist Republic, the women queried responded with an average of 2.6; in the Byelorussian Soviet Socialist Republic, 2.9; while in the Uzbek Soviet Socialist Republic the figure was 4.6. The average for the entire country was 2.9.

57. The expected number of children frequently turned out to be less than the "ideal" number, which may be best illustrated by the following example covering the above-mentioned Union Republics.

<sup>3</sup> "Zhenshchiny v SSSR", *Vestnik Statistiki*, No. 1 (1973), p. 81.

<sup>4</sup> E/CONF.60/SYM.1/35.

58. As is clearly seen from table 5, the expected number of children considerably deviates from the "ideal" number of children in family. This difference is caused by a complex of social, economic, cultural and other factors.

TABLE 5. WOMEN DISTRIBUTED ACCORDING TO "IDEAL" AND EXPECTED NUMBER OF CHILDREN IN FAMILIES

	<i>Average number of children</i>			
	<i>USSR</i>	<i>Ukrainian Soviet Socialist Republic</i>	<i>Byelorussian Soviet Socialist Republic</i>	<i>Uzbek Soviet Socialist Republic</i>
"Ideal" number of children . . . . .	2.9	2.6	2.9	4.6
Expected number of children . . . . .	2.4	2.1	2.4	4.3

SOURCE: *Vestnik Statistiki*, No. 6 (1971), pp. 26 and 30.

59. It has been mentioned above that a considerable birth-rate decline is taking place, as compared with the pre-revolutionary period. While an even more considerable mortality decrease, which was 29.1 per cent in 1917 and 8.6 per cent in 1972, took place, it was not accompanied by a sharp fall in the crude birth rate, and thus led to steady population increase.

60. The Soviet State strongly favours population increase, because in a progressing socialist economy it is one of the most important factors in the increase of national wealth and in the raising of the level of living. The economic development of the USSR is the best evidence of this fact. By 1972, the total population of the country had increased by 56 per cent, as compared with 1913; fixed assets production in all branches of the economy increased 23 times during the same period, industrial production increased 105 times, gross agricultural production three times and national income 51 times.

61. It would be appropriate to mention that, if it had not been for the wars, the economic development of this country would have been even more striking.

62. The conclusion, thus, may be drawn that the socialist way of economic development is a safeguard of a higher rate of production of material goods and services in society, which by far exceeds the rate of population increase. The socialist way of development also guarantees a continuous raising of the well-being of people and the meeting of their cultural needs, exerts a decisive impact on family development based on equal rights of men and women and helps to combine harmoniously individual and collective needs.

## POPULATION POLICY AND THE FAMILY: THE LATIN AMERICAN CASE\*

### *Centro Latinoamericano de Demografía\*\**

#### POPULATION POLICIES AND THE FAMILY: SOME BASIC CONCEPTS

##### *Towards a definition*

1. There has been a great deal of discussion in Latin America about a definition of "population policies". This can be explained by the complexity and ambiguity of the field more than by a Byzantine eagerness for conceptual perfectionism. The following considerations attempt to clarify this problem and to establish the minimal conceptual basis necessary to the development of our subject.

2. The majority of the proposed definitions have an evident normative character, which is to express what, in their authors' opinion, a population policy should be. Even though these propositions do not coincide in all their aspects, they contain certain basic common elements that can be conveniently outlined as follows:

(a) For a population policy to exist, it must pass from a passive attitude, in which population phenomena are considered as parameters, to an active attitude, in which the possibility of exerting influence or control over population variables is established;

(b) The variables which that policy is intended to influence ultimately are the volume, growth, structure, mobility and the geographical distribution of the population;

(c) A population policy is based on decisions adopted by the public sector.

3. From a normative point of view, there is general agreement that the objectives of a population policy and the means chosen to implement them should be coherent with the goals and objectives of economic and social development and subject to them. This is the reason why—it is said—a population policy should be formulated in the context of global planning.

4. In practice, the identifiable population policies usually do not fulfil this last requirement because there is no global development policy, because the planning organisms do not exist, or because when both exist the decisions destined to influence demographic behaviour are taken from a purely sectoral perspective (for example, as a component of health policy).

5. The three basic elements on which there appears to be consensus permits one to construct an operational definition in the following terms: population policy in a country exists when the public sector adopts decisions deliberately designed to influence demographic variables, whether as their principal effect or as a foreseen side-effect.

6. An even wider definition could be as follows: population policy exists when the public sector (or government) considers population variables from the point of view of their eventual control. An even stricter one than the preceding would be: "when the public sector adopts decisions . . . and implements and carries them out".

7. In this series of definitions, more or less exacting, the deliberate character of the decisions is emphasized—which is, of course, inherent in the very concept of policy—thus excluding the so-called "implicit population policies" that appear to be more appropriately called simply "demographic effects (unforeseen) of economic and social policies". It is evident that policies which directly or indirectly produce demographic effects have existed and will always exist, but it is only correct to speak of population policies when the demographic effects are foreseen and desired or, at least, accepted by the political actors.

##### *Stages in the formulation of a population policy*

8. A population policy thus defined involves at least four stages:

(a) Analysis of the problem;

(b) Formulation of a policy: taking decisions in order to influence (or not to influence) demographic variables in the desired manner, which implies fixing more or less precise goals and electing means;

(c) Implementation and enforcement;

(d) Evaluation.

##### *Analysis of the problem*

9. It is usual to speak abstractly of "the population problem", which from a political point of view is practically useless. The simple intensity of a phenomenon (for example, high birth rate) does not constitute a problem in itself but to the extent that its impact upon economic and social variables makes it an obstacle to the accomplishment of determined objectives.

\* The original text of this paper (E/CONF.60/SYM.II/12) was submitted to the Symposium on Population and the Family, Honolulu, 6-15 August 1973.

\*\* Santiago, Chile.

10. The analysis of the problem thus necessarily involves a certain conception—scientific or impressionistic—of the way the structure and dynamics of population influence economic, social and political structures and processes, thereby obstructing or facilitating the accomplishment of the proposed objectives for development.

11. Therefore, it can be affirmed that the manner of structuring a demographic phenomenon as a problem and its political significance will vary between one country and another, depending not only upon the objective situation, but upon the style or strategy of development adopted by each Government and the conception that the political actors may have of the role of demographic variables in the social, economic and political processes. Yet, according to how well or poorly integrated and extensive such a conception may be, there will be a tendency to formulate the problem as a whole or partially. In the latter case, the problem of the growth of the process of internal migration (spatial location, urban growth) is separated from that of international immigration and emigration. In practice, this is what usually occurs which is why it is more appropriate to speak of population problems and policies than of "the problem and the policy".

#### *Policy formulation*

12. With regard to this, it is necessary to mention at least two basic considerations.

13. First, because of the very nature of the variables one desires to modify, the specific goals of a population policy cannot be considered valuable in themselves. Any value these specific goals may possess arises from their connexion with the objectives of development. Thus, it is possible to maintain that the objectives intended to direct and justify a given population policy are economic, social or political, but by no means demographic. That is why the desired decrease of fertility in certain cases is sought not for itself, but because it is expected to reduce the rate of increase in the demand for services or to raise the level of family life, or to diminish pressures upon the political system etc. This apparently obvious affirmation has great importance as it establishes a clear difference between the population policy and other policies, such as health, education, employment, social security or housing, which can be instrumental in reaching broader objectives, but are oriented towards goals considered valuable in themselves. This fact justifies the relative autonomy of these policies in relation to a general development policy and, as its counterpart, justifies the subordination of an eventual population policy to that general policy.

14. Secondly, it is pertinent to point out that though the goals of a population policy may be precise and specific (for example, to reduce the birth rate from  $b_1$  to  $b_2$  in  $t$  years), thus clearly distinguishing it from other policies, the means that can be used are so varied that the population policy will be intertwined with other specific policies because of the necessity of acting

through them. This dependence is particularly intense when one attempts to modify reproductive behaviour, which is obvious if one reviews the multiple factors on which it apparently depends, such as marriage laws (which influence the age of marriage eligibility); social security systems (which reward or punish large families); programmes for maternal health (which facilitate contraceptive practice); educational and employment systems (which establish the economic significance of the child and affect women's participation in the labour force etc.).

15. Therefore, it can be maintained that, because of the very nature of variables involved, a population policy necessarily interacts and is expressed concretely through other sectoral policies (health, education, industrialization, agrarian policies etc.).

#### *Family policy and population policy*

16. The preceding discussion can be fully applied to the relations that should exist between a family policy and a population policy. The central objective of the former can be formulated as the creation of the most favourable conditions for the establishment and adequate functioning of families in accordance with the function and specific role assigned them by each society. It is evident that, universally, one of these functions is procreation, whose regulation by the couple through family planning constitutes a value in itself, a duty and a right that currently no one discusses.

17. Similarly, there is agreement that responsible parenthood is not limited to birth control, but is expressed as well and principally in the care, feeding, education and socialization of the children. Consequently, family planning programmes should be considered one among multiple instruments used by a family policy intended to enable and motivate the couple to exercise a responsible parenthood. The existence of education and services devoted to family planning is thus fully justified as a tool of family policy, regardless of whether a population policy already exists and whatever its goals may be.

18. These policies can be complementary or in conflict. Conflict arises in some cases when the demographic effect resulting from the eventual implementation of the family planning programme is considered in opposition to what the Government desires. This is the case in Argentina, where for a long time there has existed strong resistance, based on a pro-natalist attitude toward official development of such programmes. In other cases, the conflict may arise at an ethical level when, in order to raise the demographic efficiency of the family planning programmes, proceedings that are contrary to the principles and values that shape the family policy are adopted.

19. These types of conflict can also be present in other specific policies to the extent that the demographic changes that may be foreseen as a lateral effect of their application do not have the meaning or intensity appropriate to the adopted population goals.

### *Population policy and general development policy*

20. As was pointed out in paragraph 3, there is agreement that population policies should be consistent with the goals and objectives of economic and social development and subordinate to them. This proposition could be applied equally to any other particular policy, but is specially important in the case of population policies because at the same time that it gives them meaning it is essential for their rationality and effectiveness. The remainder of this paper is devoted to this latter aspect, especially referring to those population policies that affect and are affected by family dynamics and structure, that is, those attempting to influence reproductive behaviour.

21. The relation of population policy and the general development policy can be specified for the levels mentioned in paragraph 8: analysis of the problem, policy formulation, implementation and evaluation.

22. Thus far, the prevailing tendency has been to discuss population problems considering mainly or exclusively the effects of demographic factors on political, economic and social structures and processes. This perspective, though necessary, appears to be incomplete, as dynamic analysis of population problems within concrete societies should also include the study of the demographic changes resulting from changes in the economic and social factors produced by the application of specific policies (among other causes). Only this approach permits one to predict the probable course of demographic behaviour throughout time, thus establishing an important basis as much for the definition of the problem as for deciding on the desired direction of change and the goals that should orient an eventual population policy.

23. Therefore, the definition of the problem, as well as the formulation of a rational population policy, requires an answer to the following series of questions:

(a) *The analysis.* Which are the probable demographic effects of a determined economic and social policy *X* within a given historical context? To what extent is it going to affect differently the behaviour of different social sectors?

(b) *The problem.* Is the demographic behaviour that is expected to result from the application of that policy *X* favourable, indifferent or unfavourable to the achievement of the proposed objectives of development?

(c) *Objectives and goals.* Depending upon the answers to the previous questions, what should be the objectives and goals in a population policy that attempts to be an instrument of the adopted general development policy? Is it suited to reinforce or rather to counteract the demographic effects expected to result from the implementation of *X*, and in which social sectors?

(d) *Means.* Which are the changes to be effected in the proposed concrete programmes in *X*, in order

that its demographic effects could be more closely linked to the adopted population goals? Which complementary actions could be applied? Which are the necessary conditions (economic, social, cultural) for a chosen specific means to produce the desired effect? What is the political and administrative feasibility of the means (or programmes) adopted? What is the cultural and ethico-juridical acceptance of these means?

24. The scientific answer to these questions requires a theory of the interrelation of economic, social and political variables, on the one hand, and demographic variables, on the other hand, as well as a great deal of empirical research in this field. There are no answers of universal validity, and the answers vary not only as a function of the objective situations in each country, but according to the development policies adopted and the strategy chosen to implement them.

#### FACTORS OF REPRODUCTIVE BEHAVIOUR: POSSIBLE MEANS OF ACTION

25. Reproductive behaviour, as all human behaviour, is the result of the interaction of many social factors of different kinds. If it is to be modified in a given direction, one is faced with the problem of the most appropriate means to induce that change. This problem cannot be solved rationally without formulating a theoretical framework for the factors that determine or condition that behaviour and its interrelations. As the majority of the Latin American countries still maintain high rates of demographic growth, attention is centred upon those means which can be useful to induce a decrease in fertility.

26. Two main types of changes in fertility can be distinguished: the "major" changes, which have appeared in processes of demographic transition in various forms according to the different historical contexts in which they have occurred; and the "minor" changes, which are produced in different social sectors once the transition is over or within each of its stages. Discussion is directed to the factors that account for those "major" changes and to the means that can be used to induce or accelerate them. In this section, there is first a brief examination of the process of demographic transition observed in developed countries in order to take advantage of that historical experience to then outline an analytical framework that distinguishes and organizes the factors that appear to determine or influence changes in fertility.

#### *Demographic transition in developed countries*

27. The processes of demographic transition experienced by developed countries began from a stage of high fertility with a predominant orientation towards relatively large families, sexual behaviour without habitual contraceptive practice and with the expectation and acceptance of pregnancy if it resulted. Ultimately, the process has reached a stage of low fertility resulting principally from orientation towards a small family

achieved through sexual behaviour characterized by habitual contraceptive practice or by resort to abortion as an anticipated solution.

28. It should be pointed out that there were no important technological advances in the field of contraception during this process and that control of reproductive behaviour was achieved despite the primitiveness and insecurity of the methods used. One could thus conclude that the emergence of this new pattern basically followed a change in motivation from an orientation towards large families to an orientation towards small families.

29. This change in motivation appears to have responded to a change in family structure resulting in turn from important changes in the economic-social context. These changes, beginning with an initial economic-social structure in which high fertility is functional for the family, ended with a structure in which low fertility is functional.

30. In the initial structure, the cost of an additional child is small compared with his contribution through early incorporation in work and his participation in the domestic economy; the wide net of family relations was an important factor of security and of social and economic power, the children caring for and protecting their parents in old age etc. The family fulfilled a series of economic and social functions mainly through the woman, whose domestic work was considered consistent with the requirements of her role as a mother.

31. In contrast, in the final structure, economic and social factors are such that a reduced number of children becomes more functional than a large number for the satisfaction of family needs and the couple's expectations. This type of structure is characterized by (among other features) a high degree of industrialization, urbanization and urban concentration; the growing influence of urban culture on rural areas; universal primary education; the transfer of a great part of the traditional family's socio-economic function to extra-familial institutions; the tendency to lessen the difference in sex roles, with an increasing participation of women in extra-domestic work, in professional training and in political, union, artistic, athletic and other types of organizations. In these circumstances, the cost of an additional child is high, the quality rather than the quantity of the children (education, professional training etc.) is important and the social utility of the net of family relations is diminished.

32. Undoubtedly, the decline of mortality played an important role in the transition, especially as it permitted the same final family size to be achieved with a lower rate of fertility. Nevertheless, the decisive factor for the beginning of a generalized reduction in fertility seems to have been the change in the socio-economic structures which led to a reformulation of reproductive behaviour patterns, with a period of transition and adjustment.

33. It would be simplistic to believe that the developing countries must undergo the same process of

socio-economic change experienced by the developed countries in order to produce an orientation towards a small family and a practice of controlled reproductive behaviour, for at least theoretically it is possible to imagine other societal models that would lead to this kind of reproductive behaviour. What it does appear legitimate to conclude is that demographic transition to a great extent appears to be the result of important changes in the socio-economic structure and that this aspect cannot be left out of the discussion of the means to induce or accelerate the transition in specific societies.

#### *Factors of reproductive behaviour*

34. Based on the preceding general considerations, the following analytical framework is proposed, in which the discussion of instruments of action is placed.

35. The change in fertility implies two complementary elements—fertility goals (orientation towards a small family) and means to achieve them (contraceptive practice, including sterilization and abortion)—as shown in the figure given below. The significance of the figure is explained below.

#### *Factors influencing fertility goals*

36. The factors influencing fertility goals are as follows:

(a) *Structural factors at a macro-level:* elements or characteristics of socio-economic structures conditioning the family structure that determine the most functional number of children for that family. Among these factors are:

(i) in the economic structure: forms of ownership of the means of production and land tenure; types of enterprises; structure of labour force demand (in particular, job opportunities for women); forms and levels of remuneration; labour stability, etc.;

(ii) permeability of social stratification, with the corresponding mechanisms and expectations for social mobility;

(iii) educational system: costs, access, length of obligatory education, possibilities of technical training for women etc.;

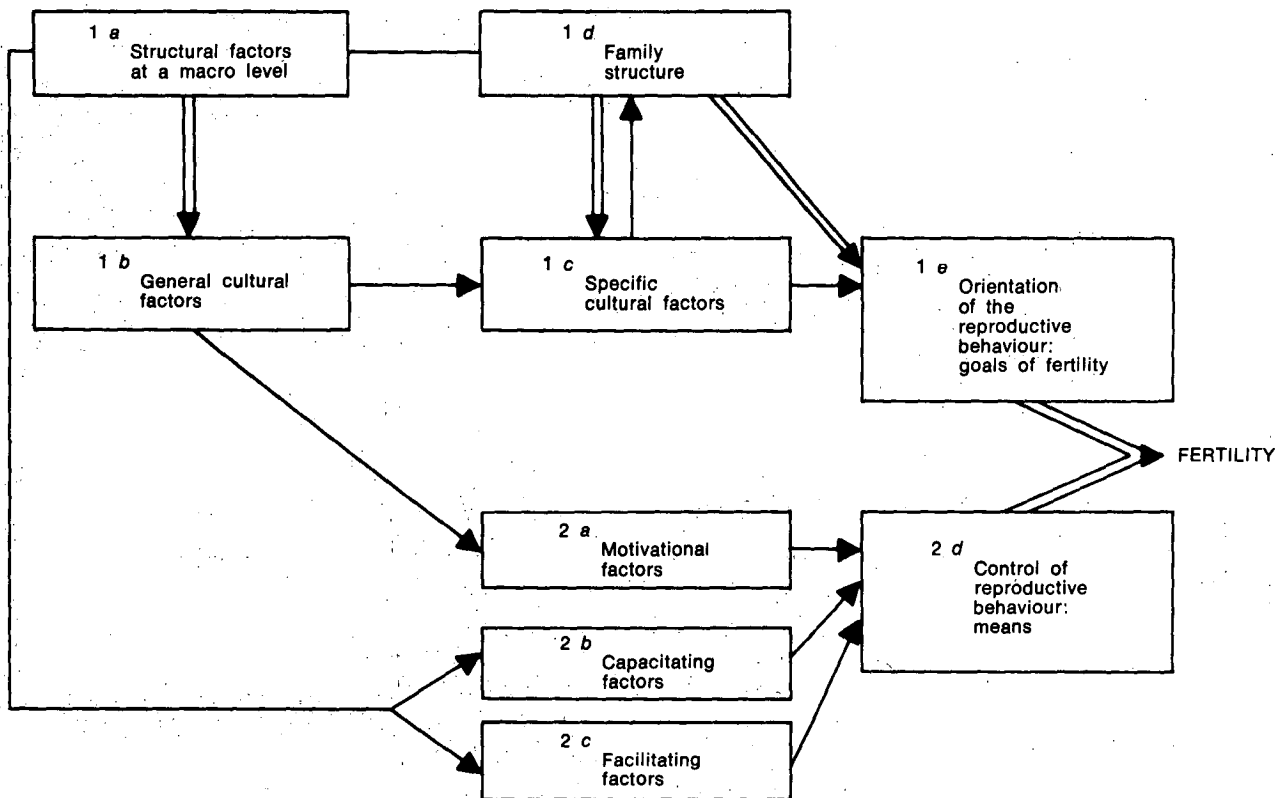

(iv) social security system: access to health services, family lending services, protection in old age, etc.

(b) *General cultural factors:* principally the traditional or modern character of the system of values and norms;

(c) *Specific cultural factors:* beliefs, values and norms referring to family size, functions, and the roles of its members, particularly the children;

(d) *Family structure:* functions fulfilled by the family and the system of roles organizing the activity and interaction of its members;

(e) *Orientation towards reproductive behaviour:* within the proposed framework, the orientation of reproductive behaviour towards a small or large family will depend principally upon the type of family struc-

ture (1 *d*) and secondarily on specific cultural factors (1 *c*). In other words, it is assumed that orientation of reproductive behaviour depends upon the significance of the children (quality *versus* quantity, differential significance according to sex etc.) to the development of family life and the satisfaction of the couple's needs, which in turn depends upon family structure. It is also assumed that family structure depends principally upon structural factors at the macro-social level (1 *a*), and only secondarily on cultural factors (1 *b*).

37. The level and form of insertion of a family unit, or of a group of family units corresponding to a social sector, in the socio-economic structure results in a particular configuration of these economic and social factors which condition the family macro-structure. The greater the internal heterogeneity of the macro-structure, the more differentiated the configurations of socio-economic factors that result from different levels and forms of insertion of the units in the structure. This, in turn, generates different types of family structure, especially with regard to forms of participation by the man, the woman and the children in extra- and intra-family economic activity.

#### *Factors influencing means towards a controlled reproductive behaviour*

38. The factors influencing means towards a controlled reproductive behaviour are as follows:

(a) *Motivational factors*. These factors condition the acceptability of techniques and can be cultural (opposition to the use of contraceptives for moral

reasons, resistance to methods involving handling of the genitals by a physician) or of widespread practical judgement (low efficiency, fear that a method may produce illness etc.);

(b) *Capacitating factors*. These factors are related to information on the existence of methods and techniques and to the aptitude and training of people for their use;

(c) *Facilitating factors*. These factors have to do with the development of technology (contraceptive methods, abortion techniques etc.) and with the availability and access to that technology.

#### *Means of action*

39. To date, the most frequently used means to induce a decline in fertility have been family planning programmes. Together with these, some measures have been taken to liberalize legislation on abortion and to facilitate its practice. These programmes act basically at the level of facilitation (2 *c*), and capacitation (2 *b*), for controlled reproductive behaviour. In many cases there are attempts to reinforce them through propaganda and education designed to introduce the norm of a small family. Thus, the intention is to induce a cultural change by acting directly on the contents of culture.

40. At a motivational level (2 *a*), means to increase the acceptance of the method have been proposed by various authors<sup>1</sup> and adopted in some programmes, as

<sup>1</sup> See B. Berelson, "Beyond family planning", *Studies in Family Planning*, No. 38 (February 1969).

in India, for example, where men have been given economic incentives to accept vasectomy. The imagination of some authors has been working feverishly at this level, inventing innumerable possible means, in many cases of a coercive nature. An example of this is a proposed law forbidding each couple to have more than two children; adherence would be ensured by an obligatory temporary sterilization for everyone, which would be suspended only between marriage and the birth of the second child.<sup>2</sup> Others have proposed obligatory sterilization after the third child, or compulsory abortion. The efficiency of these different measures may vary greatly according to the characteristics inherent in the groups or social sectors to be influenced.

41. If the use of coercive measures—the ethico-legal acceptability and political feasibility of which appear to be very low, at least in Latin America—is excluded, it can be argued that the efficiency of family planning programmes will greatly depend upon their response to a demand to a need to limit family size.

42. If the theoretical propositions mentioned above are accepted, this felt need to limit the size of the family will depend to a large extent upon the characteristics of the configuration of economic and social factors resulting from their particular form of insertion in the macro-structure. Thus, if there endures a configuration in which a relatively large number of children is functional for the satisfaction of the needs of the couple or of the family in general, the acceptance of the programme can be expected to be low. Even though family planning were to be accepted, contraceptive practice would only be casual or sporadic, without producing a significant decline of fertility.

43. The same can be expected of those measures destined to induce directly the change in cultural norms and values through propaganda. As long as having many children continues to be convenient for the couple, the cultural norms favourable to a high fertility will continue to be functional and for that very reason will show a high resistance to change. When, on the contrary, changes have already been produced at a structural level making a small family more functional than a large one, but norms favourable to a large family continue to be culturally valid, the predisposition toward cultural change can be expected to be greater (given the nonfunctional character of the norms) and therefore the efficiency of propaganda and education intended to modify them could be greater as well.

44. The use of direct incentives raises another type of problem. The appearance and generalization of a controlled reproductive behaviour pattern, oriented towards a small family, appears to require as a necessity an appropriate socio-economic configuration. If this structural condition is not met, the changes in behaviour resulting from direct motivation of the individual through incentives will probably be only changes

in aggregations of individuals without impact at cultural level. This will mean, therefore, that the possibility of such changes in a pattern of behaviour being spread and being transmitted from one generation to another will not be brought about. Thus, they would be exogenous actions incapable of producing a self-sustaining effect. On the contrary, if structural conditions favourable to a change in the reproductive behaviour are produced, direct incentives can effectively contribute to begin and accelerate the process of change, counteracting at the motivational level underlying culturally based resistance.

45. Concerning coercive measures (for example, prohibition of having more than  $x$  children, together with sterilization and/or compulsory abortion), their efficiency will depend upon the coercive capability of the authorities. However, they present serious problems from the point of view of their ethico-legal and cultural acceptability and political and administrative feasibility.

46. This short discussion of the means that can be used to implement a policy oriented towards reducing fertility can be summarized in the following propositions:

(a) Inducement of reduction in fertility supposes as a necessary condition the creation of structural conditions that make a small number of children more functional than a large number for the satisfaction of family needs;

(b) Given that the change in cultural factors is often a delayed effect of change at a structural level, situations are produced in which the effectiveness of facilitating and capacitating actions towards controlled reproductive behaviour are hindered mainly by culturally based resistance. In these cases, the process of generalized adoption of the new type of behaviour can be accelerated through means acting at the cultural level, such as propaganda and education;

(c) In specific circumstances, direct incentives can favour and accelerate the adoption of controlled reproductive behaviour, but they do not appear capable of inducing by themselves a stable generalized change that registers at the level of cultural norms and values;

(d) The creation of structural conditions favourable to a change in reproductive behaviour depends upon the course followed by its conditioning factors at a macro-structure level. This course depends, in turn, upon the action on these factors through economic and social policies. This is why consideration of the probable demographic effects of economic and social policies should become an element in the formulation of population policy and the basis for its insertion within general development policy.

#### THE SOCIAL CONTEXT: MAJOR LINES OF SOCIAL CHANGE IN LATIN AMERICA

47. This is not the place to give a detailed version of the changes that have been taking place in Latin America and that influence the family and its repro-

<sup>2</sup> E. R. Chasteen, *The Case for Compulsory Birth Control* (Englewood Cliffs, New Jersey, Prentice-Hall, Inc., 1971).

ductive behaviour. However, it is necessary to point out at least their major lines, since the society they help to form constitutes the context in which the family is found, a context without which it is difficult to make an analysis of the role of public policies in demographic change.

48. The main point to be stressed here is that the countries of the continent show, in different degrees, an increasing structural heterogeneity, regional as well as sectoral and in social stratification. This heterogeneity is manifest in the presence within the boundaries of a country of groups with characteristics similar to those found in countries economically more advanced, while other groups still cling to traditional patterns of life. In other words, it is emphasized that the problems that various authors have attempted to explain through the concepts of "marginality", "internal colonialism", "dependency" and "structural heterogeneity" cannot be left aside when one tries to analyse the family and its reproductive behaviour in Latin America.

49. The existence of an internal polarization is not a new phenomenon in Latin America, but its character has changed through time due to the double influence of the changing internal structure and the way in which national economies stand in the world economic market. Thus, while the countries of Latin America based their economy on agriculture and on exportation of some raw materials, the foci of development were constituted in those places and regions where such activities were carried out and in the cities that served them as centres of administration. As is well known, this situation changed when, due to the great depression, the political *élites* of some of the countries of greater relative development in the continent began to evolve a new style of development based on import-substituting industrialization. It was then that the heterogeneity began to acquire its more defining characteristics.

50. At first, that industrialization was centred upon the production of consumer goods, which naturally led to the establishment of factories in or around the more populated cities. The new job opportunities created by the installation of these factories drew manpower from the countryside and smaller cities to these centres. To this must be added the deterioration that the agricultural sector began to suffer due to an archaic land-tenure system, the subordinate role it began to play in the plans of the various Governments and the consequent drop of public and private investment in the sector. This situation, added to the rapid growth of the rural population, increased the surplus of agricultural manpower. The consequence of both processes is that urbanization acquired an accelerated pace as is shown by the fact that the urbanization rate of the continent increased from 1.26 for the decade 1920-1930 to 2.5 for the decade 1950-1960.<sup>3</sup>

<sup>3</sup> M. Villa, *América Latina: Algunas consideraciones demográficas del proceso de metropolización, 1900-1960*, Series C, No. 122 (Santiago, Centro Latinoamericano de Demografía).

51. This process of accelerated urbanization has, in turn, resulted in the concentration of the population in a few comparatively large cities, if not in only one. This tendency, according to some sources, has increased instead of diminished in the great majority of the Latin American countries.<sup>4</sup>

52. The tendencies described above lead to two different types of heterogeneities or polarizations: the urban-rural and the interurban. As a consequence, the economic, administrative, social, political and cultural infrastructure of the countries of the continent are concentrated in a few cities.

53. Intra-urban imbalances must be added to these polarizations. The emergence of manufacturing as an internally important sector increases the complexity of the urban social stratification. The changes expected by the experience of the more advanced countries (emergence of urban managers as an economically important group, enlargement of the "middle sectors", emergence of an industrial proletariat) are joined by others which give the Latin American urban social structure its specific characteristics. In general, they are related to what Raúl Prebisch has called "the spurious absorption of manpower" or dynamic insufficiency of the Latin American economy,<sup>5</sup> that is to say, the incapacity experienced by the economies of the countries of the region to supply steady employment to the available labour force.

54. More specifically, there are two main tendencies that the specialists mention in this respect. On the one hand, it is pointed out that the economic structure presents deep internal heterogeneities, both in sectoral productivity and in the degree of concentration found within each sector. Firms and sectors using advanced technology based on an intensive use of capital coexist with other comparatively primitive firms and sectors and with others of an intermediate development. On the other hand, and directly derived from the latter, there are deep intra- and intersectoral differences in capacity to absorb the labour force, the most modern enterprises showing the greatest incapacity in this respect.<sup>6</sup>

55. Structural heterogeneity has helped to produce the subcultural or institutional differences which to a

<sup>4</sup> See J. C. Elizaga, "Migración interna, migración y movilidad, el proceso de urbanización", in *Actas de la Conferencia Regional Latinoamericana de Población* (México, 1970), vol. 1, p. 497.

<sup>5</sup> R. Prebisch, *Transformación y desarrollo*, "La gran tarea de América Latina" (Santiago, Chile), 1970.

<sup>6</sup> In a study on the subject, it is pointed out that the modern economic sector of Latin America absorbs one eighth of the labour force while generating half the product. The contrary occurs in the traditional sector, which accounts for one third of the employed population, though not generating more than 10 per cent of the product. See *Estudio económico de América Latina, 1968, Algunos aspectos de la economía latinoamericana a fines de la década de 1960* (United Nations publication, Sales No. S.70.II.G.1). Interesting antecedents on the structure of the labour force appear in Kirsch, "Employment and the utilization of human resources in Latin America", United Nations Economic Commission for Latin America, Social Development Division, Population Unit, November 1972.

greater or lesser degree are found in all Latin American countries. The countryside and the city, urban as well as rural classes and strata, the degree of technological development of the sector or firm where people work and different historical heritages, all contribute to produce distinct values, beliefs and norms. These factors have influenced the family and its reproductive behaviour.

56. Certain social sectors still present high fertility rates. These are the populous, working class, urban sectors and the sector of the peasantry linked to the *minifundio-latifundio* system (see para. 75). The reproductive behaviour of both sectors contrasts sharply with that shown by the urban middle classes, generally oriented towards a small family and where the practice of birth control has become habitual. They are, therefore, key sectors for an eventual demographic change.

#### STRUCTURAL HETEROGENEITY, KEY SECTORS FOR DEMOGRAPHIC CHANGE AND POPULATION POLICIES IN LATIN AMERICA

57. The increasing structural heterogeneity that has characterized the social and economic development processes in Latin American countries during the past 50 years has become apparent also in changes in reproductive behaviour. Whereas middle urban sectors, principal beneficiaries of the economic development and the expansion of services (education, health, social security) have experienced a gradual and sustained decrease in fertility, to the point of reaching levels quite similar to those of the developed countries, the great bulk of the rural population, left out of the principal benefits of development, still shows high levels of fertility and, in some cases, also of mortality. Within the urban context, it has been also possible to detect a remarkable contrast between the reproductive behaviour of the middle sectors and that of the populous working class sectors, which display levels of fertility very similar to those prevailing in the rural areas.

58. If a population policy, oriented towards decreasing the birth rate, is proposed, it appears evident that the key social sectors on which the action should concentrate are precisely those which maintain high levels of fertility. In other words, if the idea is to obtain an important slow-down in the growth pattern of the Latin American population, it is necessary to induce a change in the reproductive behaviour of the working class sectors, both in urban and in rural areas.

#### *The urban context*

#### *The family structure of the urban working class*

59. Thorough examination of these urban working-class sectors (which was possible thanks to several studies carried out during recent years<sup>7</sup>) shows that

<sup>7</sup> Among these studies, it is necessary to mention: J. Duque and E. Pastrana, *Las estrategias de supervivencia económica de las unidades familiares del sector popular urbano: Una investigación exploratoria*, Programa de Intercambio Escuela Latino-

structural heterogeneity is also present within them, as determined by different positions within the economic sector. This appears to be the key factor for the differentiation of two family types: the working-class or proletarian family and the marginal or subproletarian family.

60. In general, these studies tend to agree that there are important differences relating to the type of occupation of the household head. In those families where the household head suffers permanent instability in his working performance, is underemployed and receives the lowest income on the scale, the studies have encountered the greatest number of unstable and consensual unions.

61. The insufficient income of the household head leads the mother and children to become involved in productive activities.<sup>8</sup> When the entire active female population is taken into account, one finds that women prefer to work outside the home and that married women or consensual partners participate less in economic activities than do spinsters, widows, or separated women. However, as concerns the type of marginal or subproletarian family under discussion, the preceding studies appear to demonstrate that this generalization is not applicable. Apparently, legal dispositions are operating to produce effects distinct from those desired. In this case, the regulations on pre- and post-natal leave would work as a break on hiring married women.

62. However, in the case of marginal families, studies have encountered a greater incidence of consensual unions, a situation generally not covered by the law, which makes it difficult for employers to calculate *a priori* the risk of pregnancy for the woman.

63. However, mothers within the urban marginal strata typically carry out activities not covered by social security or in contexts where it is easy to evade control by the authorities. Consequently, the legal arrangement that is apparently an obstacle would not affect the mother of an economically marginal household.

64. Participation by mothers in economic activities involves as a consequence a redefinition of authority

americana de Sociología (ELAS) CELADE (Santiago, January 1973); A. Gurrieri y otras, *Estudios sobre la juventud marginal latinoamericana* Santiago de Chile Editorial Universitaria; and, Mexico City, Siglo XX, 1971), as well as H. Godoy and F. L. Lira, "Aspectos sociológicos de la familia en Chile", *Revista de Estudios Jurídicos*, 1973; A. Mattelart and M. Mattelart, *Juventud chilena: Rebeldía y conformismo* (Santiago, Editorial Universitaria, 1970); P. Covarrubias and M. Muñoz, "Algunos factores que inciden en la participación laboral de las mujeres de estratos bajos", Instituto de Sociología, Departamento de Trabajo y Organizaciones, Universidad Católica, Santiago, Working paper No. 2, 1972; and A. Mattelart and M. Mattelart, *La mujer chilena en una nueva sociedad* (Santiago, Editorial del Pacífico, 1968).

<sup>8</sup> A comparative investigation on urban fertility in Latin American cities directed by the Centro Latinoamericano de Demografía found that in all of them, active women carried out mainly manual activities; and, excluding Buenos Aires and San José, especially non-specialized manual occupations. At the same time, it was found that either they had no formal education or had only completed several years of primary education.

roles in the marginal family in general, but especially in those organized as a consensual union. The actual exercise of authority with regard to the children and the representation of the family to the outside world fall primarily on the mother. According to some, this leads to a greater insecurity and frustration of the male, channeled as aggression towards the women and children, and as slight participation in household activities.<sup>9</sup>

65. Frequent absences of the mother from the home bring about norms of socialization different from those of other families. Older children and neighbours are those who principally fill the role of socializing agents. The former are charged with caring for the younger children, preparing meals and cleaning house. When they are not at home, because they in turn are working, the neighbours assume the tasks vital to the survival of the smallest children. Mothers and older children are the principal internal socializing agents for the family, while neighbours are the principal external agents.

66. The preceding patterns differ from those in families where the household head carries out stable manual activities, preferably of an industrial nature. A first difference arises with respect to the type of union. Duque and Pastrana<sup>9</sup> and Torres-Rivas<sup>10</sup> agree in pointing out that in these families also consensual union has enjoyed ample legitimacy, but that its incidence would tend to diminish. Several factors combine to produce this situation. On the one hand, the husband's activity allows the family an easier access to benefits provided by social security legislation and, in general, by all legislation designed to protect the family. As many of the benefits of these laws require legal matrimony, couples who for years had lived together without legalizing their union found themselves impelled to do so in order to gain access to these benefits. On the other hand, it has been pointed out that there exists a close relationship between the power of trade unions and the insurance and social security benefits they have obtained for their members. Labourers with stable work, comparatively high wages and membership in a generous system of social benefits in fact find themselves much closer to the middle class than to the other sectors of manual labourers, the marginal and underemployed. In the Chilean case, many of them have even obtained a legal definition as "employees" (white-collar) rather than "workers" (blue-collar), independent of their type of work. All this leads to an attempt to adopt the standards of behaviour and life-style of "employees", that is, standards and style of the middle class which do not permit simple consensual unions.

67. The internal division of roles is clearer in families of this type. The husband is the economic

support of the family and the mother assumes the functions of socialization. When the wife works, she does it sporadically, part-time and usually in activities that entail a greater degree of specialization than activities carried out by marginal mothers. The standards of authority are shared by both partners, with the mother maintaining them within the house and the father making decisions that go beyond the family context. The children are freed from the tasks of socializing their younger siblings and from the necessity of interrupting their studies in order to work and contribute to the family income.

68. The studies mentioned previously also note certain differences with respect to the way in which the children's role is defined. In both types of families, the mothers see the acquisition of a higher level of education than they themselves have achieved as a means of assuring upward social mobility for their children. However, in those cases where the household head carries out unstable economic activities, the aspiration to give them a better education conflicts with the necessity to work from an early age and/or help with domestic chores. The consequence of this is that many young people are forced to abandon school in the early years of primary education. In contrast, the children of fathers with more stable and better paid occupations have a greater possibility of finishing their primary education. In the case of the family that has been called here "urban-marginal", the children are considered providers of income for the immediate support of the family, whereas in industrial workers' families, there is a tendency to see them as an eventual aid in bettering the future social position of the family.

69. The role assigned to the children clarifies a more subtle aspect, but, nevertheless, one of great consequence: the temporal orientation of family activity. In marginal families, the necessity of daily survival, instability towards the future, difficulties of access to the benefits of social legislation, and, in general, all the factors that have been mentioned previously, contribute to a short temporal dimension of their activities and aspirations. Realistically, given their situation, these families do not plan long-range activities, lacking a vision of goal in the future towards which they can orient their actions. In contrast, greater economic stability, more active participation in unions and community organizations, the real rise in level of living that some have experienced, greater participation in the durable goods market and instalment buying, all contribute to a broader time dimension for the families of industrial workers. The existence of long-range goals and the possibility of achieving them gradually makes the actions of these family groups much more open to planning than those of marginal families.

70. All the contrasts that have been exposed among families in the urban manual strata, according to type of occupation of the household head, allow one to draw the conclusion that these families constitute distinct categories. Seen in the wider context of effects caused

<sup>9</sup> J. Duque and E. Pastrana, *op. cit.*

<sup>10</sup> On this topic, there is an especially interesting study by E. Torres-Rivas, "Familia y Juventud en El Salvador", in A. Gurrieri y otros, *op. cit.*, pp. 195-281.

by employment, income distribution, insurance and social security policies, these categories appear to be a consequence of the increasing closeness they have produced between the middle class of non-manual workers and industrial workers and, vice versa, the fact of unemployment and underemployment in the cities has caused an increasing gap between the employed industrial worker and the unemployed and underemployed.

#### *The change in reproductive behaviour in the urban popular sectors*

71. Up to this point, the analysis leads one to think that, should the theoretical assumptions so far made be valid, the tendency to change reproductive behaviour would be different for the two family types that have been characterized.

72. Bearing in mind the structure of the working-class family and the characteristics of the social context in which it is placed, a reduced number of children seems to be more functional than a large one, in order to satisfy its needs and to achieve its aspirations. This leads one to think that the continuance in some cases of permanent high levels of fertility in this type of family is due, on the one hand, to the persistence of cultural values and norms oriented toward a numerous family; and, on the other hand, to the lack or insufficient development of factors that permit a controlled behaviour or facilitate its practice.

73. Situations like these make it understandable that the decrease of birth rate in such sectors is often initiated with a growing resort to abortion which, given prevailing legal conditions and the restrictions of medical institutions, is carried out clandestinely and in unsanitary conditions, meaning a high risk for the mother's life. Such situations demonstrate the existing tendency towards a reduced family or at least towards the desire not to increase the family group with a new child and also that the appropriate means of reaching such an objective are lacking.

74. Therefore, a high degree of receptivity for family planning programmes can be expected from this type of family because ultimately they satisfy a felt need. Should there be underlying cultural resistance, it can be removed through education and propaganda, thus making conscious a need which arises from the very structure of the family and its context.

75. The situation of the marginal family is not so clear. The orientation towards a high fertility is supported not only by traditional cultural patterns frequently internalized in their original rural context, but by certain advantages derived from a large number of children. These advantages may neutralize to some extent the disadvantages that a large family in the urban environment must put up with (high costs of food, cramped and wretched housing etc.).

76. So it appears that, though minor changes in fertility in the marginal strata can be achieved through the diffusion of family planning programmes or the

liberalization of abortion laws, it should be difficult to obtain a permanent and generalized orientation towards a small family unless their marginal situation in the economical and social structure can be fundamentally modified. From this point of view, the population policy cannot be formulated unless it is supported by other policies oriented to modify the structural conditions that will finally determine the demographic dynamics.

#### *The rural context*

77. It is possible to identify different kinds of socio-economic contexts in the rural areas of Latin America, as well as various kinds of agricultural exploitation and a great variety of types of family structure. The conditions discussed here refer to peasant families linked to forms of land tenure and exploitation that are usually denominated as *minifundio-latifundio* complex. However, these considerations can also be valid for other types of situations.

78. The social structure in this context is characterized as bi-classist, with a very low interstrata permeability and consequently limited expectation of social mobility, except by migration towards urban centres. The peasant either possesses his own small plot of land (*minifundio*) or profits from a piece of land of the large estate (*latifundio*) in exchange for part of the family's labour. The *minifundio* owner, due to the normally very reduced size of his farm, sells part of the family's labour to the *latifundio* owner. The working salary usually is given mainly in kind or in benefits (use of a house, food for the animals etc.) with a little monetized and self-consumption economy predominating. Access to health and education services, in particular, is usually very limited, as is access to social security.

#### *The family structure*

79. Predominating in this context is the extended family, reinforced in the fulfilment of its multiple economic functions, of socialization and protection by an active set of kinship relations. The woman, besides performing an active socializing role, usually also participates in agricultural and economic activities together with the other members of the family. In this respect, it must be noted that the work performed by a woman out of the house is not incompatible with her role as a mother. This is due, on the one hand, to the fact that the working conditions are generally flexible, are near home and include the possibility of being accompanied by the children; and, on the other hand, that the responsibility of fulfilling the maternal role is diluted within the extended family.

80. In this kind of family structure, the children play an active economic role from early childhood. Their maintenance cost is low, due to the predominating forms of self-consumption. In this case, having a large number of children contributes positively to the economic efficiency and importance of the family group; it gives stability to the social position of the

family in expanding the set of kinship relations and, in this way, it also gives stability and security to the couple in their old age.

81. The decline in mortality experienced during the past decades, through advances in medical technology and the extension of health programmes, has produced an increase in the number of surviving children. It would appear, however, that this phenomenon has been more than neutralized by the migratory flow towards the cities<sup>11</sup> that frequently separates the eldest children from their homes, thus reducing the size of the family nucleus living around the parents. It can be concluded that this phenomenon helps to stimulate fertility.

#### *The change in reproductive behaviour in the peasant family*

82. In the type of peasant family that has just been described, the absence of reproductive control and its direct consequence, a large number of children, seem to be rational behaviour or at least cannot be labelled as irrational. This is due to the characteristics inherent in the socio-economic structure in which this family develops and to their particular situation in it.

83. In this context, the absence of a behaviour designed to control births is primarily due to a lack of need for it. As a consequence, the demographic acceptance and efficiency of the programmes designed to capacitate and facilitate controlled behaviour can be expected to be very low if they are not accompanied or preceded by changes at the macro-level which determine the type of prevailing family structure and the

<sup>11</sup> A survey of the marginal population taken at Santiago, Chile, shows that the greatest relative frequency of migration to the capital occurred among women between 15 and 19 years old and among men between 20 and 24 years old. See *Fecundidad y anticoncepción en poblaciones marginales*. (Santiago, Centro para el Desarrollo Económico y Social de América Latina; and Buenos Aires, Editorio Troquel, S.A., 1970).

corresponding orientation towards a large number of children. The same can be said of those programmes designed to induce direct changes at the level of norms and values of reproductive behaviour (factors at the cultural level).

#### *Population policies and other public policies*

84. The analysis of the preceding sections leads one to state, first, that in order to achieve an important slow-down in the current growth rate of the region, it is necessary to induce a profound change of reproductive behaviour in the marginal urban sectors and among the peasants. Secondly, it seems improbable that this change can be induced in these social sectors solely through resort to actions destined to capacitate and facilitate controlled reproductive behaviour (such as family planning programmes), without a radical modification of the prevailing structural conditions that allow a high fertility to be convenient for the functioning of the family and satisfaction of the couple's needs.

85. Assuming this situation, one is faced with the problem of which macro-social factors should be modified and through which policies.

86. This is not the place for a detailed discussion of each of the economic and social policies that could create the structural conditions for a change in reproductive behaviour. Here there is only room to point out that such policies as those of employment, agrarian reform, education, social security and health would appear crucial to the creation of macro-structural conditions favourable to a decline in fertility. Whether this objective is achieved will depend in great part upon the form, content and coverage given these policies. This, in turn, will depend upon whether the population policy is formulated and implemented in strict inter-relationship with social and economic policies.

## CULTURAL AND DEMOGRAPHIC INFLUENCES ON THE AFRICAN FAMILY

G. K. Nukunya\*

1. The family is without doubt the basic social unit in traditional and modern Africa, as in other parts of the world; but in almost all known societies of the continent it functions within the context of wider social units, most of which are, like the family, also based on kinship affiliations such as descent groups, extended families, secret societies and age sets. While one of the major functions of the family, the procreation of new members, is, by definition, the sole responsibility of those members occupying the positions of husband-father and wife-mother, the other major function of socialization is usually shared with wider social units. Yet, though on the surface, the two roles may appear to be separate, each one affects the other and both in turn the family cycle and size. Thus, the type and size of the wider social unit involved in the socialization process (e.g. adults within the extended family) can influence the number of children in each family, which in turn will affect the size of extended family and descent groups.

2. Although the size and complexity of political groupings can affect the nature and size of the wider social units, their effects on the family cycle are not crucial. It is true that descent groups and kinship ties appear to play a less prominent political role in centralized political systems than in non-centralized ones,<sup>1</sup> but political systems do not necessarily affect the nature of family life. Aristocratic and commoner families may exist side by side in the same society; and, in the main, their structure and organization fall under the same general umbrella of the society's norms of kinship organization. Much more important perhaps are the values associated with family life, family size, residence, descent, age of marriage and spacing of children, which do not appear to vary with types of political organization. In fact, in all these spheres one would be tempted to postulate that African family values show

greater conformity than differences.<sup>2</sup> If this premise is accepted, the conflict between traditional ideals and the demands of modern living would become very instructive and substantial.

3. Marriage in the traditional set-up is primarily for procreation and the larger the number of children, the greater the prestige of the spouses, and the more useful it is in economic and social terms for the descent groups and other wider kinship units. Plurality of wives serves to enhance these ideals by buttressing their economic foundations. Today not only have the values themselves undergone changes, but the economic factors of the present, as well as education and Christian teachings, militate against large families and polygyny. The direction of some of these changes depends to a large extent upon the system of descent, that is, whether the society is patrilineal or matrilineal in its organization. In patrilineal societies, marital bonds are close, with the spouses closely identified with the agnatic groups. Modern conditions place less emphasis on the extended family ties and descent group affiliations, while the nuclear family becomes more isolated and apparently more closely knit. In matrilineal societies, on the other hand, the minimal role played by the father in traditional jural relations within the family is giving way to greater responsibility towards the children and a lessening of the avunculate. Here again, the trend is towards a gradual isolation and solidarity of the nuclear family.

### BASIC FEATURES OF TRADITIONAL AFRICAN FAMILY LIFE

4. The most important common element in traditional family ideals is the high value placed on children. Fertility in both men and women is greatly cherished, while childlessness provokes sad and agonizing reactions from relatives, in particular, and from the community at large. Childlessness may not necessarily result from barrenness as the incidence of stillbirths and infant mortality was high. The most effective insurance against childlessness therefore became, within the limits of culturally defined rules, the fullest utilization of the reproductive potential. At the same time, there are numerous and varied sexual taboos which greatly control sex life, thereby limiting the reproductive capacity.

\* Senior Research Fellow in Sociology, Institute for Statistical, Social and Economic Research, University of Ghana, Accra.

<sup>1</sup> African political systems have been divided into centralized and non-centralized systems. The former are those which have centralized authority, administrative machinery and judicial institutions—in short, a Government—and in which cleavages of wealth, privilege and status correspond to the distribution of power and authority. The other group consists of those societies in which there are no sharp divisions of rank, status or wealth. M. Fortes and E. E. Evans Pritchard, eds., *African Political Systems* (London, Oxford University Press, for the International Institute of African Languages and Cultures, 1940), p. 15.

<sup>2</sup> Lucy Mair, *African Marriage and Social Change* (London, Oxford University Press, 1969).

5. By far the most widespread among these limiting factors is the weaning taboo found in almost all African societies. This taboo derives from the belief that the semen contaminates the mother's milk, which then becomes dangerous for the infant's health. It is therefore imperative for the mother to renounce sex throughout the period of breast-feeding, which ranges from two years to over three years. As Africans feel that a man, as opposed to a woman, cannot abjure sex for this period, this taboo serves as a pretext for men to indulge in polygyny and adultery.<sup>3</sup> It means regulating the reproductive processes of the co-wives in such a way that while one wife is breastfeeding her child, the others will be in a position to provide him with sexual services.

6. A less common practice is the generational taboo by which a woman is expected to stop childbearing as soon as one of her own children begins to have children. This is said to prevent conflict between age and generational seniority among close relatives.

7. Age of marriage is another limiting factor, especially for men. As a rule, for first marriages, men marry much later in life than women. Marriage for women in most societies takes place soon after puberty, usually between 16 and 18 years. For men, however, 20-plus appears to be the ideal and, in fact, the practice.<sup>4</sup> Thus, whereas women are given the opportunity to begin their reproductive activities as soon as they are known to qualify biologically, the same opportunity is not available to a man, thus greatly limiting his reproductive potential.

8. Polygyny is also generally believed to be a factor affecting the reproductive process and, in turn, the size of the family and households. Although for most African groups it is a method of providing more children per husband or household, and quantitative data exist to support this view, several studies have shown that polygyny, in fact, has a lowering effect on reproduction,<sup>5</sup> due to the fact that the over-all reproductive potential for any given society is based not on children per husband but rather on a per-wife basis. Comparison between women in monogamous and polygamous unions shows that in more cases than not the former are more fertile.<sup>6</sup> It is, however, difficult to give an unqualified confirmation of this because of the fragmentary nature of the data and other variables which may have affected the reproductive process. However, the data published so far indicate that polygyny does have a lowering effect on fertility.

<sup>3</sup> G. K. Nukunya, *Kinship and Marriage Among the Anlo Ewe*, Monographs on Social Anthropology, No. 37 (London, School of Economics, 1969), p. 159.

<sup>4</sup> There is no uniformity in the application of this rule. Some societies, such as the Nyakyusa, emphasize it more than others, e.g., the Ewe.

<sup>5</sup> V. R. Dorjahn, *The Demographic Aspects of African Polygyny* (Ann Arbor, University of Michigan Press, 1954), pp. 310-370; V. R. Dorjahn, "Polygyny in African demography", in W. R. Bascom and M. Herskovits, eds., *Continuity and Change in African Cultures* (Chicago, Chicago University Press, 1959), pp. 109-110.

<sup>6</sup> V. R. Dorjahn, *The Demographic Aspects of African Polygyny*, *loc. cit.*

9. The effect of this factor on the size of descent groups, however, is more favourable than on the population size as a whole. Here again, though, a distinction has to be made between patrilineal and matrilineal societies. A plurality of wives in a patrilineal society will increase the number of children per husband, while in a matrilineal society it will decrease the fertility of the women and thereby adversely affect the size of their descent groups.

10. Though polygyny is an old established form of African family life, its incidence and intensity in traditional Africa have not been accurately ascertained. But the popular conception of polygyny, that every man has a large number of wives, is far from correct. In the main, the proportion of polygynous men among the total married male population is less than half and the common numbers of wives per polygynous husband are two and three.<sup>7</sup> Only chiefs and wealthy men exceeded this level. In a study of two Ewe-speaking rural communities in 1962, about 70 per cent of polygynous husbands had only two wives in a population in which 42.4 per cent of married men were polygynous.<sup>8</sup>

11. Marital stability, another important factor in fertility, is also a function of variations in descent organization. According to the famous Gluckman hypothesis, marriage is likely to be more stable in societies organized on a system of corporate patrilineages than in others.<sup>9</sup> In patrilineal societies, it is through women married into the family group from outside that new members are provided. These societies therefore have several mechanisms for ensuring stable marriages. Matrilineal societies do not face this problem. Though stable marriages can be satisfying to them, it is not crucial for their survival as a child belongs to its mother's descent group regardless of whether she is married.

12. Since fertility, measured per woman over a given period of years, decreases as instability increases,<sup>10</sup> it would be expected that, on the whole, societies with corporate patrilineal descent groups would have higher fertility rates than those organized otherwise. Further, as patrilineal societies outnumber others in Africa by about 4 to 1, the importance of this element in demographic studies cannot be overestimated.

13. It is common knowledge that the weaning taboo was not as scrupulously observed as the anthropologist is led to believe. This appears to hold whether one is concerned with polygynous or monogamous unions.

<sup>7</sup> G. Lindblom, *The Akamba* (Uppsala, Nordiska Afrikainstitutet, 1920), p. 81.

<sup>8</sup> G. K. Nukunya, *op. cit.*, p. 158.

<sup>9</sup> M. Gluckman, "Kinship and marriage among the Lozi of Northern Rhodesia and the Zulu of Natal", in A. R. Radcliffe-Brown and D. Forde, eds., *African Systems of Kinship and Marriage* (London, Oxford University Press, 1950), pp. 167-206.

<sup>10</sup> V. R. Dorjahn, "Polygyny in African demography", *loc. cit.*, p. 110.

As such, there were often shorter intervals between births than the weaning taboos prescribed. On the whole, therefore, biological factors of limitation rather than cultural determinants influenced spacing of children in the traditional system. Needless to say, short intervals between births greatly increased high infant mortality and poor health conditions for the family as a whole, with the notable exceptions of husbands and adult male children. All these factors must be considered within a background of generally poor medical facilities which was an essential feature of traditional Africa. It is also worthy of note that despite the hazards of reproduction and childbirth to which women are exposed, the life span of women is still longer than that of men. In Ghana, where the average life span is among the highest on the continent, the life expectancies are about 50 years for women and 45 years for men. It appears that the physical hazards of life, accidents, alcoholism and indulgence have greater effects on men than on women. Homicide and suicide also involve predominantly more men than women.<sup>11</sup>

14. Rules relating to age at marriage appear to have been more closely adhered to than other tribal prohibitions. Even here, the widespread ignorance about age must put serious question marks after such claims. What is certain in all this is the knowledge that the facts concerning modern practices are available and can be used to clarify the possible institutions and values of the past which have been suggested from inconclusive data.

15. If these qualifications are borne in mind, the essential features of African traditional family life may be listed as polygyny, the tendency towards exhaustion of female reproductive activities, different ages of marriage for males and females, inadequate health facilities and the preference for large families. The life of the family unit was short, with the number of adults and aged members disproportionately small in relation to the number of youths and young children.

#### SOCIAL CHANGE, POPULATION AND THE FAMILY

16. Although the ideals and the important elements of the traditional family have largely persisted, changes in a number of areas have also been occurring. Notable among these changes are improved hygienic conditions, Western forms of education, Christian influence and increased mobility. If, as has been suggested, inadequate health practices affected the structure of the traditional family, improvements in this sphere would also inevitably alter that structure. The most decisive effect of such improvements would be an increase in the ratio of the adult population to youths and children, and therefore longer life for the family unit. In fact, although the provision of health facilities on the continent is still far from adequate, the position is gradually improving. However, these facilities are rather unevenly distributed, with the poorer countries of the western

Sudan and Central Africa lagging somewhat behind the relatively "rich" ones like Ghana, Ivory Coast, Nigeria, Zaire etc., even though these are inadequate by world standards. If, as it is hoped, the trend towards improvement continues, some basic African attitudes will have to be seriously reconsidered in the near future. A large number of aged, for instance, would be a heavy strain on family resources, thereby threatening the African's traditional attachment to and support for his aged. Old people's homes, which to the traditional African are anathema and a cruel practice, may well become an acceptable method of caring for the aged.

17. The influences of Western education and Christianity are also tremendous. Many Africans who have been exposed to them have become alienated from many of their traditional usages.<sup>12</sup> By using modern feeding methods to supplement breast-feeding, the dangers of the weaning taboo cease to have much relevance. Polygyny has lost much of its traditional appeal. In the past, wealth consisted largely of dependants who could help in economic activities. Indeed, in many societies, the well-remembered names of the past are those of men who had several wives and slaves, whose offspring now form the core of many villages. Currently, in addition to the fact that polygyny is opposed by the churches, wealth and leadership can be obtained by other means. Moreover, polygyny demands greater expenses now than before. People who have many wives must be able to feed them. In the early days of colonialism, the few people who were able to make money had limited use for it. Giving marriage payments and buying slaves were the chief uses to which it was put. Today, there are not only many other uses for money, but it can be obtained in several other ways. It is, however, not certain whether the apparent reduction in polygynous unions would contribute much to population change. If anything, by itself, it should, according to the suggestion made in paragraph 8, lead to an increase in the over-all population. However, when viewed in conjunction with other practices which have come in the wake of Christianity and formal education, the regulation of family size and access to family planning techniques, the over-all picture may be different. The data on this score still remain inconclusive and further studies in this area are needed before a more positive assertion can be made. Moreover, it must be remembered that only a fraction of the total population is exposed to these influences, while even among this fraction many have not accepted the ideas usually associated with these important factors of change.<sup>13</sup>

18. Perhaps one of the most important factors of change affecting the family cycle is the movement of

<sup>11</sup> P. Bohannon, ed., *African Suicide and Homicide* (Princeton, New Jersey, Princeton University Press, 1960).

Forde, ed., *African Worlds* (London, Oxford University Press, 1954); Lucy Mair, *Introduction to Social Anthropology* (London, Oxford University Press, 1965), pp. 233-252.

<sup>13</sup> D. Brokensha, *op. cit.*

people to towns and centres of wage employment. The exodus is usually from economically depressed areas like Botswana, Lesotho, Malawi, Swaziland and northern and southern Zambia in central and southern Africa and the western Sudan in west Africa, while areas of immigration include the forest zones of west Africa and the mining complexes of central and southern Africa. Another form of migration that cuts across economically defined geographical boundaries is one involving school and college graduates moving into commercial, administrative and industrial centres. The latter is a permanent sort of movement involving the whole nuclear family, while most of the former involves individuals of both sexes, with males featuring more prominently.

19. Where adult males migrate from the family, as is the case in the depressed areas mentioned, the family cycle is greatly disrupted. The sex ratio is heavily tilted in favour of females; and, as a rule, households headed by women develop in large numbers. The composition of the domestic groups assumes a more complex character as adults remaining at home take charge of children left behind by migrating parents.<sup>14</sup> This is particularly true of places where school education for children has become important. Yet, the people involved may regard their participation as a function within the descent system, whether the society follows matrilineal or patrilineal rules of organization. In patrilineal societies, the core of the domestic groups is usually the nuclear family, though matriarchies can develop as a result of emigration.<sup>15</sup> In matrilineal societies, what Fortes<sup>16</sup> reports for the Ashanti appears to have wider applicability. He distinguishes three different types of household composition:

(a) Households grouped around a husband and wife. In the simplest case this corresponds to the elementary family consisting of a man, his wife and their children, but other kinsfolk may be included in the group;

(b) Households grouped around an effective minimal matrilineage or part of it, such as a woman and her sister or daughter, or a man and his sister or sister's son;

(c) Households made up of a combination of the previous types, e.g., a household consisting of a man and his wife and children as well as his sister's children. This finding is largely supported by other studies of matrilineal societies, especially those in the matrilineal belt of Central Africa.<sup>17</sup> It is important to remember that in all descent systems the family unit itself is not static. It has a growth cycle by which its initial sim-

licity in terms of composition is greatly affected in later years.<sup>18</sup>

20. Migration of the whole nuclear family may also have its disruptive consequences, especially on the extended family and the descent group. Gaps develop in the personnel performing essential group functions and substitutes have to be employed. Younger members may have to perform functions traditionally reserved for the very old and vice versa. Duties usually performed by families standing in specific structural relationship with or within the group may fall into the hands of any available relatives regardless of whether their structural position merits it. For instance, in one Ewe community terribly afflicted by emigration, one of the four wards in the town was so completely depleted that it cannot now function without the assistance of others. At dances and funeral rites the active co-operation of people from other wards is always sought.<sup>19</sup>

21. Divorce rates and marital stability have also been affected by contemporary social changes. The sanctions that made for stability in the past have undergone considerable modifications or have been completely destroyed. Well-knit, stable descent groups and strong family ties, as well as such practices as the levirate widow inheritance, sororate, sororal polygyny and the so-called "house property complex", which all helped to stabilize marriage in the past, have been drastically curtailed. Social norms have become more flexible. As a result, marital stability even in traditionally stable societies has been greatly reduced. Studies of marriage and social change in a number of societies have generally supported this view.<sup>20</sup> As far as the family cycle is concerned, the effect of this development will be a tendency towards further reduction in the fertility of women.

22. While social changes continue to affect African institutions relating to population and the family, systematic efforts by Governments, in the form of family planning programmes, have been under way throughout the entire continent. People are now being exposed to birth-control measures in a manner which makes their acceptance quite easy. In Ghana, for instance, the pill and other forms of birth control are subsidized through governmental support to meet the pockets of any one in need of them. It is reasonable to assume that, in the initial stages of official government participation in this exercise, those who really need services, namely the poor and the rural folk, would not readily comprehend the significance of the programme. However, with greater education, it is difficult to see how an all-out effort by Governments

can fail to alter radically people's attitudes. Needless to say, modern family planning and birth-control measures directed principally towards regulating family size and, by extension, the over-all national figure do not tally with traditional ideas. However, economic factors are now forcing people to put reduced value on large families and to emphasize rather the quality of life of the families they have. Childlessness and barrenness, loathed in traditional Africa, still provoke the same reaction but a one-child family, instead of being considered a liability, may well become an asset in the future. Today, the educated *élite* appears to have accepted the new gospel, while the poor, battering under the sweat of economic pressures, are still in the consideration stage. Still, it is fair to assume that a general acceptance in the not too distant future is not a misplaced optimism.

#### CONCLUSION

23. Social structure and population affect each other. The rules that govern the organization of society are essential factors in population size and change. They determine the extent to which external and internal forces of change can be accommodated within a particular structural framework. At the same time, changes, when they do occur, tend to generate social consequences which affect the structural framework

itself. In traditional Africa, the family ideals, epitomized by emphasis on large families, were related to other aspects of the social structure, namely, the extended family system, descent groups, respect for age etc. The quest for large families was closely related to a number of restrictive mechanisms on reproductive activities, such as the weaning taboo. Again, the family ideal used to be greatly affected by the poor hygienic conditions and inadequate medical facilities which greatly contributed to high infant and over-all mortality. All in all, the traditional emphasis on a large number of children had to contend with many negative influences. Yet, with a high mortality rate it was the only sure way of survival.

24. Today, the emphasis has shifted considerably, not only in attitudes and ideals but in the structure. Contemporary factors of change have introduced attitudes and economic conditions that require radical changes in family size and the value placed on children. The change may take a long time to cover all sections of the population. Barring unforeseen consequences, however, it appears to be an irreversible trend which will result in smaller families and a larger proportion of adults and the aged in the family in particular and in the population at large. If this happens, certain basic family ideas and attitudes, such as those concerning the treatment of the aged, would have to be altered accordingly.

## THE FAMILY AND FERTILITY CONTROL: A DISCUSSION OF SOME CENTRAL ISSUES IN THE SYMPOSIUM ON POPULATION AND THE FAMILY\*

*Judith Blake-Davis\*\**

1. In concentrating on the family, this Symposium concerns itself with the principal intervening variable between the aggregated, or macroscopic demographic behaviour of individuals as represented by birth rates, rates of growth, and population size, on the one hand, and, on the other, by individual decisions to undertake (or not to undertake) certain kinds of action, such as to use contraceptives or migrate.

2. It is at the level of individual decision to take a particular action that family planning programmes operate. It is the macroscopic level that demographers typically use for analysis.

3. In appreciating the policy importance of considering the family, one must be clear that aggregated balances of fertility and mortality are not, as far as is known, the focus of individual perception and motivation. The demographic adjustment of societies is an institutional adjustment, and it is through the components of such institutions as the family that individual motivation is structured.

4. As an example, one may give the one that has been argued recently, the relation of fertility to mortality levels.

5. Characteristically, demographers are fond of pointing out that the fertility of traditional, peasant societies has had to be high to counterbalance the high and fluctuating mortality. Those societies that were not able to produce the requisite fertility simply did not stay around. Unfortunately, some people have tended to regard this long-term evolutionary statement as a perfectly adequate explanation of the motivation of individuals. Individuals are said to be primarily motivated in their family-size preferences by the mortality situation. They want large families because of high mortality. Reduce the mortality and everyone "adjusts".

6. This view of the situation leaves out of account entirely that the way in which societies have adjusted to high mortality is through their institutional structure, not through the unlikely chance that some would, for inexplicable reasons, contain a majority of individuals dedicated to maintaining a demographic balance, whereas others would be wiped out for lack of such

altruists. Moreover, those societies that have survived have motivated individuals not merely to compensate for the average mortality situation, but to over-compensate for it and thus offset the disastrous effects of mortality peaks.

7. The institutional structure that has provided this motivation has had, however, a positive rather than a preventive focus. To be sure, the family and kinship in traditional peasant societies has functioned in such a way as to over-compensate for mortality. However, the family-size desires of individuals have been geared, independently of mortality, to a utility-cost schedule that has the family and the kinship structure as its focus. The weights in this schedule have been such as to make people want to do what the society needed—produce large families. People have been hooked into a system in which kinship and the family are ends in themselves, and are also instrumental in bringing about other ultimate goals. This fact must be understood in order to comprehend why, when mortality conditions change, the fertility response is often extremely sluggish. Indeed, as Tabbarah<sup>1</sup> has pointed out, it may be that in some peasant societies people are very far from achieving the number of living children they desire and hence a decline in mortality simply aids them in reaching their family-size goal.

8. Consider first the utilities of children in traditional, agricultural societies. These comprise not only the well-understood economic advantages, but the non-economic utilities. Individuals not only use children for labour and depend upon them for care and assistance later in life, they also gain the only rewarded statuses in the kinship system through having children and thereby becoming parents. Further, the kinship system is either pre-eminent, or among the most pre-eminent, factors in the society. Other sectors, non-kinship sectors, are typically linked with kinship in some intrinsic fashion. For example, a priestly role will simultaneously be familial rather than belonging to a celibate, or salvation will depend upon rituals performed by others after one's death rather than upon one's own conduct and efforts. Because structures alternative to kinship and the family may well be suppressed, the individual is highly dependent upon the family for protection, influence, support and social status. The more the society is

\* The original text of this paper was submitted as a Conference room paper to the Symposium on Population and the Family, Honolulu, 6-15 August 1973.

<sup>1</sup> Riad B. Tabbarah, "Toward a theory of demographic development", *Economic Development and Cultural Change* (Chicago, Illinois), vol. 19 (January 1971), pp. 257-275.

oriented around kinship, and the more other roles depend upon the basic kinship roles, then, by definition, the more the individual enjoys non-economic as well as economic utilities by creating and maintaining a family.

9. What about the costs of children? In subsistence economies, the direct economic costs of children tend to be camouflaged by a lack of the enforced accounting that a monetary system imposes. More important, the range of quality in children is likely to be held down by the over-all societal limitations. Where, for example, excellent medical and dental care are unavailable and educational facilities are marginal, the children of privilege and the children of poverty are more similar than are those in modern societies. The direct non-economic costs of offspring are also minimized by the availability of a wider kinship network to help with child-rearing, and by the fact that the authoritarian position of parents allows them to place older children *in loco parentis* with respect to younger ones. In general, the expectation is not that the parents put out enormous amounts of effort, but that they receive from children.

10. At the level of indirect economic costs, it is obvious that, given the limited opportunities for social and geographical mobility, little competes with children. Parents do not have an enormous and nagging sense of things forgone, things on which they could have spent their money or resources, had they not had so many children. Wives do not see earnings going a-glimmering. By the same token, indirect non-economic costs are restricted. The range of activities on which to spend personal energies or leisure time is circumscribed. Moreover, children do not typically compete with these as they would in a society in which such activities are often most enjoyably pursued without children around.

11. In sum, therefore, when utilities and costs are weighed, economic or non-economic, direct or indirect, a situation emerges that maximizes what the individual is likely to regard as his gain by having children in relation to other possible gains, and minimizes his costs. One must realize, however, that both utilities and costs are kept pro-natalist by means of intense social control over such elements as the roles and activities of women and youth, as well as over social and geographical mobility. An individual's family-size desires are thus "voluntary" only in the very limited sense that, given this highly controlled situation, and the implicit and explicit coercions in maintaining the utilities and costs as they are, he "chooses" to have a large family.

12. Conversely, what one wants to recognize is that the mechanism of fertility decline carries the double bind of a loss of advantages and an increase in disadvantages of children, combined with augmented parental responsibility for child-rearing. In this sense, one can say that the industrial revolution changed the ground rules for reproduction—it literally boxed parents in. Potential policy in developing countries would be capable of doing the same thing and, the present author would argue, of promoting individual welfare at the same time.

13. This discussion leads to the issue of implicit *versus* explicit policy. It is very important, in considering future explicit policies, to have a clear awareness of their current implicit counterparts. Otherwise, the possible or potential policies are judged according to Utopian criteria. It is piously averred that such planned policies must harm no one, must conform to the highest standards of human rights and must affirm the noblest goals. Meanwhile, back in the real world, existing kinship structures and systems of stratification help to consign a large share of the world's people to material degradation and psychological despair.

14. The point here is that implicit pro-natalism has had its costs, which should not be minimized when one compares it with explicit anti-natalism. To achieve the family structures one sees in actuality in developing societies, there has been a widespread subordination of individual potential: the potential of women as human beings throughout life; the potential of the young in general; the contribution of persons who do not conform to the reproductive model. The present author would argue that a benefit of low mortality is that this intense constraint over individuals is no longer necessary. Because the whole process is more efficient, it is no longer required that individuals be forced to devote so much of themselves to the business of reproduction.

15. It appears to be crucial that political leaders should realize that in their countries they are not beginning from scratch as concerns family policy and its relation to population. They are beginning from a base of existing policies, most of them favouring high fertility and social rigidity. The State, through its laws and its legitimations of public policy, is, in most developing countries, already being coercive and constricting by putting the family before the individual. In some countries, this is strongly abetted by religious organizations.

16. In supporting the familial *status quo*, politicians are thus not casting their lot with the mass of individuals, or with the rights of individuals in some abstract sense. They are casting their lot with those selected individuals who benefit disproportionately from the family structure as it now stands. And, in many countries of the world, if one looks at family structure on a status-by-status basis—older son, younger son, daughters, wives, mothers-in-law and so on—one can find that there are more people getting very little out of the family than there are getting a lot. There is, in effect, an enormous amount of exploitation of some types of family members by a very few others. It does not appear obvious to this writer that the State should regard such patterns as sacred. Nor should there be unreflecting acquiescence on the view that policies selectively attempting to change pro-natalist aspects of the family would infringe, by definition, on individual freedoms and deeply personal aspects of behaviour. The liberating effect of such policies for most individuals should be considered as well.

17. A third point that should be brought into the open because of its long-run policy implications is the reluctance of many developing countries to admit officially that they have a population problem requiring a specific population policy. They are willing to admit that they have a social and economic development problem and that this is why demographic increase appears undesirable, but they are reluctant to accord independent status to a population problem. In particular, they are unwilling to think of a distinctive policy to control fertility. It is instructive to ask why. There are, of course, many broad sociological reasons (some of which have been discussed above), and there are reasons that are idiosyncratic to the countries concerned. But there are also some reasons of particular political relevance to the World Population Year in 1974 and to the way in which world leaders are approached.

18. For one, the developed countries have helped to cause this resistance to public recognition of population issues by bearing down so hard on the problem of population growth among developing peoples. Recently, this issue has been given enormous saliency in the dealings with them; and, in the process, they have had unleashed on them a foreign family planning bureaucracy that is an independent force with which they have had to cope. In effect, a purely adventitious cost has been introduced into the receptivity to fertility control—the cost of coping with the developed countries and keeping their heavy-handed prodding in check.

19. Secondly, by exhibiting such stunning eagerness to reduce population growth in developing countries, the developed countries have set in operation what Waller called “the principle of least interest”. If people in the developed countries are so concerned, what is it worth to them to implement their desires? Leaders in developing countries cannot help but see the potential here. It is highly advantageous to take the point of view in such countries that it means more to them than to the developing world that it reduce its fertility. So, the question then becomes, how much is it worth? Can the anxieties of the developed countries be parlayed into having them underwrite all sorts of other programmes as a condition of accepting family planning, or some fertility control policies? How far can they be pushed?

20. This may appear to be a canny ploy, but with regard to an issue of such moment, it is bad business. The only healthy arrangement would appear to be for the developed countries to cease being the prime movers, to cease making developing countries think that it is more in the interest of the developed countries than in their own interest that they reduce fertility, and, hence, to cease creating an international situation in which the population issue has become a pawn.

21. Lastly, this author believes that considerable attention must be paid to the question of the way in which politicians perceive the population issue. This involves an extension to the political level of the kind of analysis that Ryder considered in relation to the family members in his paper.

22. Ryder's paper deals with a problem very familiar to social scientists—the disparity between the point of view of the actor within a system and the point of view of the observer of that system. These two points of view differ in at least two important ways. First, the actor internalizes the goals and norms—they are his and he acts in terms of them. The observer, on the other hand, studies them and their relation to behaviour. Secondly, the observer (in this case, the demographer) may study the aggregated behaviour of many actors and thus move to another level of analysis entirely from that of the actor.

23. Ryder has juxtaposed the way it looks to the actor within each family against the way it looks to the observer studying the aggregated behaviour of many families (in rates and indices); and he has attempted to show that what may be a highly disadvantageous situation in the aggregate, can, none the less, be perceived by the individual inside the family as having certain advantages.

24. This disparity of analytical visions must be extended also to the politician. Politicians as yet are poorly situated to subscribe to the analytical view of the observer concerning population increase. One reason is that this view tells about very lagged negative effects of population growth, whereas from the politician's point of view there may actually be some immediate positive effects—a large supply of cheap labour, for example.

25. Further, the politician is usually a short-run type of person. He hangs by his toes, and what will happen 25 years from now in terms of doubling and the like does not concern him so much as what will happen tomorrow. Hence, the policy issues concerning population must be presented far more in terms that bring out the immediate difficulties of population growth, rather than the long-run ones.

26. This task is not easy, and it is the Achilles heel of national population policies and one of the principal causes of sensational over-statement. In talking to politicians about population, one is competing for attention with many immediate issues. And demographers have, as yet, done poorly in presenting the case of population increase as an immediate issue. The politician must somehow come to understand the costs to him of ignoring it, rather than the costs to future generations which he can, understandably, discount heavily.

27. But for national leaders to appreciate short-run impacts of demographic events, demographers must first be able to delineate them very clearly. The present author believes that demographers have underestimated the importance of doing this if one wishes to have an effect on policy. In this regard, a concentration on the family and kinship is perhaps one of the best jumping-off points, for the family formation behaviour and decisions of young people as they currently go about creating the population growth of the future (or delay or refrain from doing so) do have impact in the here and now—for example, impact on demand for housing,

migration into burgeoning urban slums, the need for and location of public and individual health services and, perhaps above all, the skills and mobility of the existing labour force. Only if it is made clear that in discussing reproductive behaviour, one is discussing an entire institutional complex, not just fertility rates, will it be possible to begin to pin-point for others the large-scale, day-to-day effects of the organizational arrangements that produce high or low fertility.

28. In attempting to trace the short-run effects of birth rates, those rates cannot be divorced from the family structure that produces them. Birth rates are indicators of a particular kind of allocation and organization of human resources and energies. If the history

of the modern world has anything to teach the developing world, it is that the quality and organization of this human factor, rather than capital, non-human resources or quantity of labour, has been the single most important element in increasing *per capita* output and development. For the leaders of developing countries not to appreciate the daily losses incurred by allowing the energies and talents of young adults to continue to be drained into what has become functionless reproduction represents a tragic misconception. Although there may be numerous non-intellectual reasons for maintaining this misconception, demographers can make a genuine contribution by providing the factual documentation for dispelling it.

**Part Seven**

**POPULATION AND HUMAN RIGHTS**

## UNITED NATIONS STANDARDS CONCERNING THE RELATIONSHIP BETWEEN HUMAN RIGHTS AND VARIOUS POPULATION QUESTIONS \*

*United Nations Secretariat \*\**

1. Taking a broad view of the subject, it perhaps might be possible to assert that all or almost all the instruments concerning human rights adopted by or under the auspices of the United Nations bear some relation to population problems. However, in order to help the reader gain a clear understanding of what might be regarded as the guidelines for United Nations normative work in the field of human rights and population, and also because of limitations on documentation, this analysis concentrates on those standards which, in the light of the preparatory work, would appear to have the clearest and most direct influence on the three demographic variables: fertility, mortality and migration. The word "instrument", in accordance with the generally accepted practice of the United Nations, refers to conventions as well as resolutions adopted by the United Nations General Assembly or by special conferences convened by the United Nations to which all Member States have been invited. The word "standard" is used in a broad sense and does not in itself imply any judgement as to the legal nature or scope of the provisions studied. Most of the standards dealt with in this document have been reproduced *in extenso* in *Human Rights: A Compilation of International Instruments of the United Nations*.<sup>1</sup>

2. Several instruments adopted by or under the auspices of the specialized agencies appear to be relevant to the relationship between human rights and population questions. Some of these instruments are reproduced in the above-mentioned compilation. This paper simply mentions, in each section, various instruments of the specialized agencies purely for the purpose of illustration. The same applies to various instruments of regional intergovernmental organizations.

3. Before beginning the detailed analysis of the standards concerning fertility, mortality and migration, it must be stressed that these standards cannot be isolated from the fundamental purposes and principles of the United Nations as embodied in Articles 1 and 2 of the Charter. In particular, one should always bear in mind the principle of non-discrimination, which has been set forth clearly in the Charter itself (Article 1,

paragraph 3, and Article 55 c) and reaffirmed in various instruments including the Universal Declaration of Human Rights, the two international covenants on human rights<sup>2</sup> and the International Convention on the Elimination of All Forms of Racial Discrimination (particularly article 5, paragraphs (b), (d) (i) to (iv) and (e) (iv)).

### UNITED NATIONS STANDARDS CONCERNING THE RELATIONSHIP BETWEEN HUMAN RIGHTS AND FERTILITY

4. Consideration should certainly be given not only to the provisions adopted by or under the auspices of the United Nations which are analysed below, but to certain instruments of the specialized agencies, in particular, the constitutions of the World Health Organization (WHO) and the United Nations Educational, Scientific and Cultural Organization (UNESCO), and several resolutions adopted by those two organizations on various questions relating to family planning,<sup>3</sup> and to some International Labour Organisation (ILO) conventions. Among the instruments adopted by regional organizations, some articles of the European Social Charter<sup>4</sup> (particularly articles 16 and 17) and the European Convention for the Protection of Human Rights and Fundamental Freedoms and the Protocols relating to it<sup>5</sup> could, it would appear, be taken into consideration, as could articles 1 and 17 of the American Convention on Human Rights.<sup>6</sup> The draft principles drawn up by the Second Asian Population Conference, held at Tokyo from 11 to 23 April 1973 (see document E/CN.11/1065) and other instruments drawn up under the auspices of the regional economic commissions of the United Nations should also be taken into account.

<sup>2</sup> International Covenant on Economic, Social and Cultural Rights and International Covenant on Civil and Political Rights (General Assembly resolution 2200 A (XXI), annex).

<sup>3</sup> See, in particular, the resolutions of these two specialized agencies mentioned in resolution XVIII of the International Conference on Human Rights, held at Teheran in 1968 in *Final Act of the International Conference on Human Rights* (United Nations publication, Sales No. 68.XIV.2); General Assembly resolution 2211 (XXI) and Economic and Social Council resolution 1484 (XLVIII).

<sup>4</sup> See *European Yearbook* (The Hague, Martinus Nijhoff, 1962), vol. IX, pp. 246-287.

<sup>5</sup> See *European Yearbook* (The Hague, Martinus Nijhoff, 1955), vol. 1, pp. 316-343.

<sup>1</sup> United Nations publication, Sales No. 73.XIV.2.

### *Rights relating to marriage and the family*

5. Among the provisions concerning the right of men and women of full age to marry and to found a family and the provisions relating to the place of the family in society, the following may be mentioned: article 16 of the Universal Declaration of Human Rights; article 23 of the International Covenant on Civil and Political Rights; article 10 of the International Covenant on Economic, Social and Cultural Rights; the 1962 Convention on Consent to Marriage, Minimum Age for Marriage and Registration of Marriages; and General Assembly resolution 2018 (XX) of 1 November 1965, which makes a recommendation on the same subjects.

6. One of the basic ideas to emerge from these standards is that of the freedom and equality of men and women with regard to the decision to marry and the rights they possess during marriage and at its dissolution. In particular, any limitations on these freedoms due to race, nationality or religion are expressly condemned in article 16, paragraph 1, of the Universal Declaration. These principles in themselves might extend the scope of the right to legitimate procreation (and as a result, perhaps, total fertility) considerably beyond the traditional limits which have often characterized it. Nevertheless, account should be taken of other United Nations norms which are also relevant to fertility (see, *inter alia*, the paras. 7 and 19-26 of this chapter) and might have the contrary effect.

7. Another aspect of this question concerns the minimum age for marriage. Article 2 of the 1962 Convention requires that legislative action should be taken to specify a minimum age for marriage, while General Assembly resolution 2018 (XX) of 1 November 1965 recommends, in principle II, that the minimum age should be 15 years. The desire to implement the right to free consent to marriage has also incidentally led to the prohibition of some practices similar to slavery to which women were subjected (article 1, paragraph (c), of the 1956 Supplementary Convention on the Abolition of Slavery) and to the requirement that certain procedures, including publicity and the presence of witnesses, be followed for the solemnization of a marriage (article 1, paragraph (1), of the 1962 Convention on Consent to Marriage, Minimum Age for Marriage and Registration of Marriages).

8. Several provisions stress the importance of the family, which is often described as the "fundamental group unit of society" (article 16 of the Universal Declaration) and proclaim the right of the family as such to protection. The concepts of family, procreation and childhood are closely linked in several provisions. For example, paragraph 16 of the Proclamation of Teheran states in one sentence that "the protection of the family and of the child remains the concern of the international community", and article 10 of the International Covenant on Economic, Social and Cultural Rights stresses that the "widest possible protection and assistance should be accorded to the family", particularly

"while it is responsible for the care and education of dependent children". However, none of the instruments that have been studied explicitly states that procreation is the purpose or necessary consequence of family union.

#### *The "right to decide freely and responsibly on the number and spacing of children"*

##### *Formulation of the concept*

9. Particularly since 1966, this principle has been proclaimed in various recommendations adopted by or under the auspices of the United Nations.<sup>7</sup> Particular reference should be made in this connexion to General Assembly resolution 2211 (XXI) of 17 December 1966 on population growth and economic development; paragraph 16 of the Proclamation of Teheran and resolution XVIII of the International Conference on Human Rights held at Teheran in 1968; article 4 and article 22, paragraph (b), of the Declaration on Social Progress and Development (General Assembly resolution 2542 (XXIV) of 11 December 1969); and section II C, paragraph 4, of the programme of concerted international action for the advancement of women (General Assembly resolution 2716 (XXV) of 15 December 1970).

10. The preamble of resolution 2211 (XXI) of 17 December 1966 on population growth and economic development refers to a "principle" to which States should give "due regard" in their population policies, to be formulated by them in full sovereignty. In this resolution, the determination of the number of children by families is not described as a "right". In the programme of concerted international action for the advancement of women (1970), the General Assembly declares one of the "minimum targets to be achieved during the Second United Nations Development Decade" to be "making available to all persons who so desire the necessary information and advice to enable them to decide freely and responsibly on the number and spacing of their children" (section II C, paragraph 4).

11. In other instruments, the determination of the number and spacing of children is presented as being a "right". Paragraph 16 of the Proclamation of Teheran and operative paragraph 3 of resolution XVIII of the Conference on Human Rights refer to a "basic human right", a term which was endorsed by many delegates in their statements at the Conference.<sup>8</sup> The Declaration on Social Progress and Development of 1969 refers to "the exclusive right" of parents (article 4) and to the "right" of families (article 22, paragraph (b)). The

<sup>7</sup> This right was also the subject of a declaration, dated 10 December 1966, signed by 30 Heads of State or Government, which is referred to in the third paragraph of the preamble of resolution XVIII of the International Conference on Human Rights. See *United Nations Population Newsletter*, April 1968, p. 44.

<sup>8</sup> See *Summary Records of the First to Thirteenth Meetings of the Second Committee of the International Committee of Human Rights, Teheran, 25 April-9 May 1968*, United Nations document, A/CONF.32/C.2/SR.1-13.

General Assembly recommended that the Declaration be used as "a common basis for social development policies".

*Persons and authorities concerned in the determination of the number and spacing of children*

12. In some instruments, it is stated that decisions on this question should be made by "the family". Reference should be made in this connexion to the preamble of General Assembly resolution 2211 (XXI) of 17 December 1966 on population growth and economic development, and to article 22, paragraph (b), of the Declaration on Social Progress and Development of 1969.

13. The word "parents" was used in formulating paragraph 16 of the Proclamation of Teheran (1968) and also in article 4 of the Declaration on Social Progress and Development. In respect of the latter provision, it should be noted that the word "parents" was introduced by the Third Committee of the General Assembly, in preference to the word "family", which appeared in the draft of the Commission for Social Development.<sup>9</sup> During the discussion, it was stated, among other things, that in determining the number of children, the right of the parents, as the persons principally concerned and responsible, should prevail over the opinions of other members of the family (ascendant and collateral relatives), although the welfare of the family as a whole should be taken into consideration.<sup>10</sup>

14. Very close in meaning to the word "parents" is the term "couples", used by the Conference at Teheran in its resolution XVIII. One of the main reasons for this choice appears to have been the wish to include, at least by implication, the right to have no children, if so desired.<sup>11</sup> It is also worth noting that the adjective "married", which had been suggested in the course of the debate to qualify the word "couples", was not used by the sponsors, nor did it form part of the resolution as adopted by the Conference, on the report of its Second Committee.<sup>12</sup>

15. All the provisions referred to above, regardless of their differences, appear to be based on the concept

<sup>9</sup> See *Official Records of the General Assembly, Twenty-third Session, Annexes*, agenda item 50, document A/7374; and *ibid.*, Third Committee, 1599th meeting, para. 32.

<sup>10</sup> See *Official Records of the General Assembly, Twenty-third Session, Third Committee*, 1599th meeting, para. 34. It will be noted that within the framework of the Declaration on Social Progress and Development there are a number of differences in the use of certain terms, since article 4, under the heading "Principles", contains the word "parents", whereas article 22, paragraph (b), under the heading "Means and methods", uses the term "family". A number of the statements made during the discussion leading up to the adoption of article 22, paragraph (b), seem to indicate that the word "family" in this article was considered as a synonym of or very close approximation to the term "parents". (See *ibid.*, Twenty-fourth Session, Third Committee, 1682nd and 1683rd meetings.)

<sup>11</sup> See foot-note 8 above.

<sup>12</sup> The oral proposal made by India is contained in A/CONF.32/C.2/SR.1-13; see foot-note 8 above. The text of the resolution is contained in *Final Act of the International Conference on Human Rights*, chap. III, resolution XVIII.

of a right exercised in common by a number of persons.<sup>13</sup> Another formula appeared in section II C, paragraph 4, of the Programme of Concerted International Action for the Advancement of Women, adopted by the General Assembly in 1970 (resolution 2716 (XXV), annex). This text sets out as one of the "minimum targets to be achieved during the Second United Nations Development Decade" making available "to all persons who so desire the necessary information and advice to enable them to decide freely and responsibly on the number and spacing of their children". The records of the twenty-third session of the Commission on the Status of Women show that the sponsors replaced the word "couples" by the expression "all persons who so desire", principally to extend the scope of the article to cover the situation of the unmarried mother.<sup>14</sup> Paragraph 4 of section II C was adopted by the Third Committee without any discussion of this particular point. At the same time, the Assembly stressed, in one of the general clauses preceding the programme, that the family, as the corner-stone of society, must be protected.

16. The records of the preparatory work on the above-mentioned instruments contain few clear indications as to the person or authority whose opinion should prevail in the event of a disagreement between the couple or members of the family.

17. In the Third Committee of the General Assembly and in the Commission on the Status of Women, the view was expressed that, in such a case, the final decision should rest with the wife, as the person most concerned, after consultation with her husband.<sup>15</sup>

18. Various United Nations organs have, on a number of occasions, discussed whether, or to what extent, authorities outside the family would be entitled to intervene in determining the number of children. During the discussion on article 4 of the Declaration on Social Progress and Development, a number of representatives in the Third Committee maintained that the right of the parents could not be considered in isolation from the objectives of economic and social development, particularly in developing countries. Such considerations could involve a certain supervisory right or even certain persuasive activities on the part of the State in respect of human fertility.<sup>16</sup> Other representatives, on the other hand, were of the opinion that that was an "exclusive" right of the parents, which could not be subjected to any outside interference or pressure.<sup>17</sup> The Third Committee of the General Assembly adopted the term

<sup>13</sup> See, for example, *Official Records of the General Assembly, Twenty-fourth Session, Third Committee*, 1682nd meeting.

<sup>14</sup> *Official Records of the Economic and Social Council, Forty-eighth Session, Supplement No. 6*, chap. III.

<sup>15</sup> See, for example, *Official Records of the General Assembly, Twenty-fourth Session, Third Committee*, 1683rd meeting; *ibid.*, Twentieth Session, Second Committee, 1016th meeting, para. 21.

<sup>16</sup> *Ibid.*, Twenty-third Session, Third Committee, 1600th and 1601st meetings.

<sup>17</sup> *Ibid.*, 1601st meeting, para. 4.

“exclusive right” by a vote of 28 to 25 with 25 abstentions.<sup>18</sup> It is clear from the context of the Declaration, however, that this clause would in no way run counter to the dissemination of information to education or to the provision of services and means offered to parents to enable them to enjoy true freedom of choice in this matter.<sup>19</sup> The word “exclusive”, qualifying the “right of the parents” to determine the number of children, does not appear in the other relevant instruments.

*The concept of responsibility as concerns determination of the number and spacing of children*

19. In the texts adopted at the Conference at Teheran and in all the relevant instruments adopted subsequently, the concept of responsibility is linked to that of freedom. The debates offer no precise indication as to the legal or moral nature of this responsibility, nor as to the institutions and procedures that might be envisaged in order to bring about its exercise. However, various opinions were expressed on the purpose and *raison d'être* of this responsibility.

20. Many speakers emphasized the relationship between demographic development and the effective enjoyment of economic and social rights, and the need for responsible action by those concerned in order to maintain optimum population.<sup>20</sup> Such considerations are reflected in paragraphs 1 and 2 of resolution XVIII of the Conference on Human Rights. Some representatives, while recognizing the importance of those considerations, were of the opinion that a reduction in fertility would not automatically result in an increase in the level of living, but that demographic policy should be accompanied by a series of other economic and social measures.<sup>21</sup>

21. During the debates at the United Nations, this link between fertility and the enjoyment of economic and social rights and human rights in general was emphasized at various levels, in particular at the level of the couple. The opinion was expressed that parents were perfectly entitled to decide how many children they had, bearing in mind, in particular, their joint desire for well-being.<sup>22</sup>

22. Within the couple, special attention was given to the status of women and their rights. Emphasis was laid on the links between family planning, on the one hand, and, on the other, the right of women to health and well-being, to develop their personalities through education, to engage in an occupation of their own free

choice and to leisure.<sup>23</sup> Thus, in section II C, paragraph 4, of the Programme of Concerted International Action for the Advancement of Women, the General Assembly mentioned the possibility of access to “information on the ways in which women can benefit from family planning”. The work of the Commission on the Status of Women on the relationship between family planning and the advancement of women has led, among other things, to the adoption by the Economic and Social Council of resolution 1326 (XLIV), to the preparation of a wide-ranging study and to the organization of several seminars on the subject.<sup>24</sup>

23. In the opinion of many representatives, the concept of responsibility in that field should be based on the right of children, without discrimination, to parental love, well-being and education recognized in the Declaration of the Rights of the Child, proclaimed by the General Assembly on 20 November 1959. During the debates at the Conference at Teheran and at other meetings, various speakers appeared to be of the opinion that, as far as parents were concerned, this responsibility towards their own children should prevail over all other considerations in determining the number and spacing of births.<sup>25</sup> In this connexion, mention should also be made of the formula used in various instruments, for example in article 6, paragraph 2, of the Declaration on the Elimination of Discrimination against Women, according to which the interest of the child should prevail in all matters concerning the child within the family.

24. Frequent reference was made, beyond the family sphere, to the responsibilities towards society and the country;<sup>26</sup> in that connexion, specific mention was made of article 29 of the Universal Declaration of Human Rights. According to several speakers it was necessary, particularly in the developing countries, to influence human fertility through non-coercive measures in order to attain and maintain the optimum population necessary for the economic and social development of the entire country.<sup>27</sup> In that connexion, it should be pointed out that many instruments recognize the right of States to adopt whatever demographic policy they deem advisable, bearing in mind their own needs and views as concerns development, on the basis of respect for human rights. These instruments include the preamble of General Assembly resolution 2211 (XXI)

<sup>18</sup> *Ibid.*, para. 5.

<sup>19</sup> See the Declaration on Social Progress and Development (General Assembly resolution 2542 (XXIV)), article 22 (b). See also, for example, *Official Records of the General Assembly, Twenty-fourth Session, Third Committee, 1682nd meeting, para. 15.*

<sup>20</sup> See foot-note 8 above; see also *Official Records of the General Assembly, Twenty-third Session, Third Committee, 1601st meeting.*

<sup>21</sup> See foot-note 8 above.

<sup>22</sup> See, for example, *Official Records of the General Assembly, Twenty-fourth Session, Third Committee, 1682nd and 1683rd meetings.*

<sup>23</sup> See foot-note 8 above; see also *Official Records of the General Assembly, Twenty-third Session, Third Committee, 1600th meeting; ibid., Twenty-fourth Session, Third Committee, 1683rd meeting; ibid., Twentieth Session, Second Committee, 1016th meeting.*

<sup>24</sup> See *Official Records of the Economic and Social Council, Forty-eighth Session, Supplement No. 6, paras. 106-118 and resolution 7 (XXIII), and ibid., Fifty-second Session, Supplement No. 6, paras. 138-141 and resolution 6 (XXIV).*

<sup>25</sup> See foot-note 8 above.

<sup>26</sup> See, for example, *Official Records of the General Assembly, Twenty-third Session, Third Committee, 1601st meeting; and ibid., Twenty-fourth Session, Third Committee, 1683rd meeting.*

<sup>27</sup> *Ibid., Twenty-third Session, Third Committee, 1600th and 1601st meetings.*

of 1966, resolution XVIII of the Conference at Teheran in 1968; article 22, paragraph (b), of the Declaration on Social Progress and Development of 1969, paragraph 65 of the International Development Strategy for the Second United Nations Development Decade (General Assembly resolution 2626 (XXV) of 1970), and principle 16 of the Declaration of the United Nations Conference on the Human Environment held at Stockholm in 1973.<sup>28</sup> This last principle, in particular, states clearly that demographic policies must respect "basic human rights". This formula can be compared with the opinions expressed by various sponsors of resolution XVIII of the International Conference on Human Rights as reported in the summary records of the meetings of the Second Committee of that Conference (see paragraph 11 above).

25. One important aspect of the problem of the responsibility of the public authorities as concerns procreation was the subject of a rule of international law contained in article II, paragraph (d), of the 1948 Convention on the Prevention and Punishment of the Crime of Genocide. That article states specifically that "imposing measures intended to prevent births within the group" constitutes an act of genocide when such measures are taken "with intent to destroy, in whole or in part, a national, ethnical, racial or religious group, as such". Article III of the Convention states that conspiracy to commit genocide, direct and public incitement to commit and attempts to commit genocide and complicity in genocide shall be punishable, as well as the act of genocide itself. As the *Ad Hoc* Working Group of Experts on the treatment of political prisoners in South Africa, which was established under resolution 2 (XXIII) of the Commission on Human Rights, pointed out in its report,<sup>29</sup> it is clear from the preparatory work for the Convention that the intention to destroy the group as such (and not only a particular individual or family belonging to the group) is an essential component of the crime of genocide. However, it would probably be enough for the possibility of destruction to be noted and approved (*dolus eventualis*). According to the Convention, penal responsibility would exist, even if the act failed to achieve its end—the destruction of the group. Moreover, the provision requires that the measures be coercive.

26. Going beyond the framework of genocide, the question of the free consent of the persons concerned to measures affecting their fertility has been considered repeatedly by the United Nations. Article 7 of the International Covenant on Civil and Political Rights, which states that "no one shall be subjected without his free consent to medical or scientific experimentation", was adopted expressly in order to prevent a recurrence of the atrocities perpetrated against the human "guinea-

pigs" in the Nazi concentration camps.<sup>30</sup> However, as the Secretary-General stated in 1951, in a report on the fate of the survivors of concentration camps,<sup>31</sup> the judgement on "the medical experiments" handed down by one of the United States military tribunals at Nürnberg following the Second World War, demonstrated that those criminal experiments had included numerous cases of forced sterilization.<sup>32</sup> The question of free consent to medical treatment was again examined by the General Assembly in the context of article 12 of the Covenant on Economic, Social and Cultural Rights, relating to health: it was decided that a reaffirmation of the principle contained in article 7 of the Covenant on Civil and Political Rights was not necessary.<sup>33</sup>

*Dissemination of information and educational activities concerning the number and spacing of children*

27. Resolution XVIII of the Conference on Human Rights held at Teheran in 1968 is the first of the instruments studied in which the couple's right to "education and information" relative to the number and spacing of their children is expressly stated. A similar idea is found in article 22, paragraph (b), of the Declaration on Social Progress and Development, which recommends the provision to families of the "knowledge" necessary to enable them to exercise their right to determine freely and responsibly the number and spacing of their children. In section II C, paragraph 4, the programme of concerted international action for the advancement of women recommends that such "information... including information on the ways in which women can benefit from family planning" be made available to all persons who desire it.

28. Several speakers maintained that that right to information was an essential corollary of the right to decide freely and responsibly on the number and spacing of children.<sup>34</sup> Mention should be made here of the general United Nations standards on freedom of information contained in article 19 of the Universal Declaration of Human Rights and in article 19 of the International Covenant on Civil and Political Rights. In the Universal Declaration of Human Rights, article 19 on freedom of information is, like the other articles, subject to the general restrictive provisions of article 29 on the duties of the individual to the community. As to the rights embodied in article 19 of the Covenant, in addition to the fact that they may be derogated from in time of public emergency (article 4), exercise of them carries

<sup>34</sup> See foot-note 8 above; and *Official Records of the General Assembly, Twenty-fourth Session, Third Committee*, 1683rd meeting.

<sup>28</sup> *Report of the United Nations Conference on the Human Environment* (United Nations publication, Sales No. 73.II.A.14).

<sup>29</sup> E/CN.4/984/Add.18, paras. 23-30. The General Assembly commended the Group on its report in resolution 2714 (XXV).

with it "special duties and responsibilities" with a view to ensuring "respect of the rights or reputations of others" and "the protection of national security, or of public order (*ordre public*), or of public health or morals".

29. With respect to freedom of information on family planning, the question of restrictions was taken up by the General Assembly in the course of the debate on the programme of concerted international action for the advancement of women. An amendment, proposed by Saudi Arabia, was adopted whereby such information would be "based on valid and scientific expertise, with due regard to the risks that may be involved". During the discussion,<sup>35</sup> some representatives contended that, as drafted, the amendment could result in undue interference in the freedom of parents. The sponsor of the amendment, supported by the majority of representatives, maintained that the requirements of public policy (*ordre public*) concerning maternal and child health must be recognized.

30. Under resolution XVIII of the Conference on Human Rights, couples have the right not only to adequate "information", but to adequate "education" in the matter of family planning. Some of the representatives at the Conference at Teheran emphasized the importance of the educational aspect of family planning activities, including, in their opinion, appropriate sexual education.<sup>36</sup>

31. On these questions, the general United Nations standards on the right to education, including those in article 26 of the Universal Declaration of Human Rights, article 18, paragraph 4, of the International Covenant on Civil and Political Rights, article 13 of the International Covenant on Economic, Social and Cultural Rights, and principle 7 of the Declaration of the Rights of the Child, will come to mind. In various forms, those instruments recognize, in particular, the prior right of parents to choose, if not the general education, at least the religious and moral education to be given to their children in conformity with their own convictions. In the discussion in the Third Committee on the Universal Declaration of Human Rights, it was acknowledged, however, that this right of parents is subject, like other rights, to the restrictions stipulated in article 29 of the Declaration. It may be recalled, too, that article 13 of the International Covenant on Economic, Social and Cultural Rights refers to "such minimum educational standards as may be laid down or approved by the State".

32. There is no indication in the debate of the nature and scope of possible government responsibility in giving effect to the right of those concerned to necessary family planning knowledge. Literally, the formulae used in the Declaration on Social Progress and Development and in the programme of concerted international action for the advancement of women appear to invite the

competent authorities to continue their efforts to ensure, so far as possible and in accordance with methods they deem appropriate, that those concerned shall have access to such knowledge; these clauses do not appear, however, to imply that the authorities should necessarily, of their own accord, disseminate such information or organize such education.

*Provision of services and access to means for determining the number and spacing of children*

33. In article 22, paragraph (b), of the 1969 Declaration on Social Progress and Development, the General Assembly for the first time mentioned "the provision to families of the knowledge and means to enable them to exercise their right to determine freely and responsibly the number and spacing of their children". Some speakers criticized the word "means" as opening the door to all sorts of undue interference by the authorities in family matters. The majority of representatives, on the other hand, considered it essential to maintain that concept, the sole purpose of which, in their opinion, was to facilitate the parents' freedom of choice.<sup>37</sup> Some of the latter—supporters of the word "means"—indicated, further, that in their understanding the notion of the free choice of parents excluded abortion,<sup>38</sup> and that the dissemination of appropriate information and techniques would in fact lead to a reduction in the number of abortions and, consequently, in maternal and infant mortality.<sup>37</sup>

34. The word "advice" in section II C, paragraph (4), of the programme of concerted international action for the advancement of women was not the subject of wide comment during the debate; probably, however, it goes beyond the word "information", which also occurs in that paragraph.

UNITED NATIONS STANDARDS CONCERNING THE RELATIONSHIP BETWEEN HUMAN RIGHTS AND VARIOUS QUESTIONS RELATING TO HUMAN MORTALITY AND MORBIDITY

35. The United Nations norms expressing the universal aspiration towards reducing mortality and morbidity rates and prolonging life expectancy deserve to be studied as carefully as the preceding norms. The advances made by medicine in the fight against disease, and the progress made in dietetics and other sciences, are in fact the most remarkable aspects of the demographic developments which have taken place in many countries over the past 10 years.

36. Account will be taken in particular of the following provisions, which are listed in chronological order:

(a) Article 6 of the Charter of the Nürnberg International Military Tribunal of 8 August 1945, the

<sup>35</sup> Official Records of the General Assembly, Twenty-fifth Session, Third Committee, 1818th and 1819th meetings.

<sup>36</sup> See foot-note 8 above.

<sup>37</sup> Official Records of the General Assembly, Twenty-fourth Session, Third Committee, 1682nd meeting.

<sup>38</sup> Ibid., Twenty-third Session, Third Committee, 1599th meeting.

principles of which were affirmed by General Assembly resolution 95 (I) of 11 December 1946;

(b) Article II (a) to (d) of the Convention on the Prevention and the Punishment of the Crime of Genocide;

(c) Articles 3 and 25 of the Universal Declaration of Human Rights;

(d) Articles 2, 4 and 5 of the Declaration of the Rights of the Child;

(e) Article 5 (e) (iv) of the International Convention on the Elimination of All Forms of Racial Discrimination;

(f) Article 6 of the International Covenant on Civil and Political Rights;

(g) Articles 11 and 12 of the International Covenant on Economic, Social and Cultural Rights;

(h) Articles 10 (b) and (d), 18 (c) and 19 of the Declaration on Social Progress and Development of 1969;

(i) Paragraphs (68) and (69) of the International Development Strategy of 1970;

(j) Articles 1, 2 and 7 of the Declaration on the Rights of Mentally Retarded Persons;

(k) The General Assembly resolutions on respect for human rights in armed conflicts, in particular, resolution 2676 (XXV) on the protection of civilians in time of war.

37. A number of instruments of the specialized agencies, in particular the constitutions of the Food and Agriculture Organization of the United Nations (FAO) and the World Health Organization and a number of International Labour Organisation norms on health and safety at work must be fully taken into consideration. Also to be considered are WHO provisions that may have some relationship to questions concerning morbidity among different categories of the population, such as children, women, various ethnic groups, rural populations etc. As far as regional organizations are concerned, mention is made in particular of article 2 of the European Convention for the Protection of Human Rights and Fundamental Freedoms, articles 11 and 13 of the European Social Charter and article 4 of the American Convention on Human Rights as mentioned in paragraph 4 above. Lastly, the Hague Conventions of 1907<sup>39</sup> and the four Geneva Conventions for the Protection of Victims of War, of 1949,<sup>40</sup> must be borne in mind.

#### *Definition and protection of the right to life*

38. During the debates which resulted in article 3 of the Universal Declaration, two amendments designed to make it clear that the article would apply "from the moment of conception" were submitted.<sup>41</sup> Other representatives preferred a concise formulation without

<sup>39</sup> Carnegie Endowment for International Peace, J. B. Scott, ed., *The Hague Conventions and Declarations of 1899 and 1907* (New York, Oxford University Press, 1915).

<sup>40</sup> United Nations, *Treaty Series*, vol. 75.

<sup>41</sup> E/CN.4/21.

qualifications; and, in addition, some objected that such amendments could not be reconciled with certain national legislations.<sup>42</sup> The General Assembly, without taking up a position on the problem of abortion, preferred a very general formula. The discussions of article 6 of the International Covenant on Civil and Political Rights gave rise to similar exchanges of views. An amendment designed to protect the right to life "from the moment of conception" was rejected by 31 votes to 20, with 17 abstentions. Those in favour of the amendment had stressed, in particular, that the right as thus defined was protected in a number of countries and they felt it would be logical to bring the general definition of the right to life into line with the specific clause prohibiting the execution of a pregnant woman who is sentenced to death. Among the opposing arguments, it was pointed out that it was impossible to determine the exact moment of conception, that the amendment would raise delicate questions relating to the rights and duties of the medical profession, and that, in order to ensure the largest possible number of ratifications, it was preferable not to raise such a controversial matter in the Covenant.<sup>43</sup> Reference may also be made here to the passages of chapter I which note that in the Declaration on Social Progress and Development (1969) the "exclusive right" of parents "to determine freely and responsibly the number and spacing of their children" was represented by the sponsors of that wording as not including the right to abortion.<sup>44</sup>

39. The debates in the context of the Covenant concerning the limitations *ratione materiae* and *ratione personae* which should be applied to the principle of the right to life related above all to the question of the death penalty, which may be imposed by the competent courts only for the most serious crimes and is not applicable to minors below the age of 18 or to pregnant women. Moreover, the Covenant specifies that nothing in the article shall be invoked to delay or to prevent the abolition of capital punishment.

40. It will be recalled that international penal law solemnly condemned, as "war crimes", in particular the "murder . . . of civilian population of or in occupied territory [and] of prisoners of war or persons on the seas" (article 6 (b) of the Charter of the International Military Tribunal at Nürnberg) and, as "crimes against humanity", "murder, extermination . . . committed against any civilian population, before or during the war, . . . in execution of or in connexion with any crime within the jurisdiction of the Tribunal" (article 6 (c) of the Charter of the International Military Tribunal at Nürnberg).<sup>45</sup> These principles of international law

<sup>42</sup> E/CN.4/AC.2/SR.3.

<sup>43</sup> *Official Records of the General Assembly, Twelfth Session, Annexes*, agenda item 33, document A/3764, paras. 97 and 113.

<sup>44</sup> *Ibid.*, *Twenty-third Session, Third Committee*, 1599th meeting; and *ibid.*, *Twenty-fourth Session, Third Committee*, 1682nd meeting.

<sup>45</sup> The full text of this article is reproduced in *History of the United Nations War Crimes Commission and the Development of the Laws of War*, chap. IX, section A (ii) (1) (London, His Majesty's Stationery Office, 1948).

were affirmed by the General Assembly in resolution 95 (I). Mention should also be made of the two articles that are common to the four Geneva Conventions of 1949, relating to "grave breaches" of these treaties, which are defined in a manner very similar to the Nürnberg principles. Under article II of the Convention on the Prevention and Prohibition of the Crime of Genocide, which applies both in time of peace and in time of war, certain acts, including "killing members of the group" and "deliberately inflicting on the group conditions of life calculated to bring about its physical destruction in whole or in part" shall be punished as crimes under international law if they are committed "with intent to destroy, in whole or in part, a national, ethnical, racial or religious group, as such". This intentional element appears to be essential, according to the preparatory work, and it seems that *dolus eventualis* will suffice.<sup>46</sup>

41. The right to life of the handicapped, the infirm or persons suffering from incurable diseases, including mental illness, has often been considered by the United Nations. During the drafting of the Universal Declaration of Human Rights, a specific clause, based on a text by the Inter-American Juridical Committee submitted to the Commission on Human Rights, was proposed ensuring "the right to life of incurables, imbeciles and the insane" (document E/CN.4/2, dated 8 January 1947). The omission of these terms from the final text does not appear to result in any way from objections to the substance of the proposal, but rather from a concern to retain a fairly general formulation. It would also appear that the debates were somewhat complicated because of the juxtaposition of phrases relating to "the right to life from the moment of conception" in these same amendments. The Declaration on the Rights of Mentally Retarded Persons, of 20 December 1971, confirms the right of such persons to life and to the necessary care. In discussing these questions, the Commission on Human Rights and the Third Committee were fully aware of the murders and massacres by the Nazis of persons suffering from physical or mental diseases and handicaps that were regarded as incurable, for the sole purpose of reducing the number of "useless eaters" or for alleged eugenic reasons. These atrocities were punished by the Nürnberg International Military Tribunal as "war crimes" and "crimes against humanity".<sup>47</sup>

#### *Rights relating to nutrition*

42. Article 25 of the Universal Declaration mentions, among many other elements of the right to an adequate level of living, the right to adequate food. In article 11 of the International Covenant on Economic, Social and Cultural Rights, a further clarification was made by stressing "the essential importance of international co-operation based on free consent" in im-

<sup>46</sup> On these matters, see *inter alia* E/CN.4/984/Add.18, paras. 23-30.

<sup>47</sup> *The Judgement of the International Military Tribunal for the Trial of German Major War Criminals, Nuremberg 1946* (London, His Majesty's Stationery Office, Cmd. 6964), p. 60.

plementing the right to adequate food. Moreover, the General Assembly adopted at its eighteenth session in 1963, in response to an appeal from the Director-General of FAO, an additional paragraph to article 11 of the Covenant recognizing "the fundamental right of everyone to be free from hunger".<sup>48</sup> Among the specific programmes designed to guarantee this right, the full use of technical and scientific knowledge and the development or reform of agrarian systems were by general consent mentioned in paragraph 2 of article 11. A number of representatives stressed the importance they attached to the implementation of programmes designed to ensure "an equitable distribution of world food supplies in relation to need". This last provision was qualified by a phrase recognizing the problems of both food-importing and food-exporting countries. It was, nevertheless, made clear that this phrase could not be interpreted as implying that economic interests should prevail over humanitarian and social considerations.<sup>49</sup>

43. The Declaration on Social Progress and Development of 1969 reproduced these principles, which, among others, should serve as "a common basis for social development policies". Under the heading, "Objectives", the Declaration mentioned in article 10 (b) the elimination of hunger and malnutrition. In the section "Measures and methods", article 18 (b) and (c) recommended the implementation of democratic agrarian reforms in order to boost agricultural production and also the equitable distribution of food.

44. Paragraph (69) of the International Development Strategy of 1970 provides that the Governments of the developing countries should make an effort, through appropriate programmes and with international assistance if necessary, towards meeting their nutritional requirements, *inter alia*, by stepping up the production and distribution of high-protein foods.

45. Perhaps even more than other economic and social rights, the right to adequate food enshrined in United Nations instruments is closely linked to the right of a people not to "be deprived of its own means of subsistence" proclaimed in paragraph 2 of article 1 of the International Covenant on Economic, Cultural and Social Rights. The General Assembly has declared in resolution 1803 (XVII) that "the right of peoples and nations to permanent sovereignty over their natural wealth and resources must be exercised in the interest of their national development and of the well-being of the State concerned."

#### *Rights relating to health*

46. Article 25 of the Universal Declaration proclaims, among others, the right of everyone to a level of living adequate for his health and the right to the necessary medical care. This general text was found

<sup>48</sup> *Official Records of the General Assembly, Eleventh Session, Annexes*, agenda item 31, document A/3525, para. 133; *ibid.*, *Third Committee*, 742nd and 743rd meetings.

<sup>49</sup> *Ibid.*, *Eighteenth Session, Annexes*, agenda item 48, paras. 89, 90, 101 and 103.

preferable to certain more detailed drafts which specified in particular the duty of States to take measures designed to protect health and prevent disease.

47. Under the terms of paragraph 1 of article 12 of the International Covenant on Economic, Social and Cultural Rights, the States Parties recognize the right of everyone "to the enjoyment of the highest attainable standard of physical and mental health". This formulation is less detailed than the text proposed by the Commission on Human Rights, inspired by the Constitution of WHO, in which health was defined as "a state of complete physical, mental and social well-being, and not merely the absence of disease or infirmity". Although a number of speakers declared their support for such an extended concept of health, stressing, *inter alia*, the importance of its social aspect, the majority of the General Assembly apparently was of the opinion that there was a risk that any definition would be incomplete.<sup>50</sup> Paragraph 2 of article 12 describes certain types of steps which should be taken to achieve the realization of the right to health, including "the creation of conditions which would assure to all medical service and medical attention in the event of sickness".

48. The Declaration on Social Progress and Development (1969) deals twice with rights relating to health. Article 10 (d) proclaims as one of the "objectives" to be pursued respect for the highest standards of health and the provision of health protection for the entire population, "if possible free of charge". In the section, "Means and methods", article 19 (a) of the Declaration refers to "The provision of free health services to the whole population".

49. In the context of the International Development Strategy (1970), paragraph (68) provides, *inter alia*, for the continuation of a concerted international effort to eradicate by the end of the Second Development Decade, from as many countries as possible, at least one of the diseases that still seriously afflict mankind.

50. The United Nations has adopted special provisions relating to the health and well-being of certain classes of persons, in particular women in pregnancy, children and the physically and mentally handicapped.

51. Lastly, it should be mentioned that in resolution 2842 (XXVI) of 18 December 1971 the General Assembly requested the Secretary-General to prepare, in co-operation with interested specialized agencies, a report suggesting guidelines for national policies and international action related to the needs and the role of the elderly and the aged in society in the context of over-all development.

#### UNITED NATIONS STANDARDS CONCERNING THE RELATIONSHIP BETWEEN HUMAN RIGHTS AND MIGRATION

52. The problems relating to migration, both at the national and at the international level, have been the object of frequent discussions at the United Nations.

<sup>50</sup> *Ibid.*, Eleventh Session, Annexes, agenda item 31, document A/3525, paras. 145 and 151.

The following instruments, in particular, contain provisions on the subject:

(a) Universal Declaration of Human Rights: articles 2, 4, 9, 13, 14, 15, 21, 23 and 29;

(b) International Covenant on Civil and Political Rights: articles 1, 2 (1), 4, 8, 9, 12, 13, 22, 25, 26 and 27;

(c) International Covenant on Economic, Social and Cultural Rights: articles 1, 2, 7 (a) (i), 8 (1) (a), and 25;

(d) International Convention on the Elimination of All Forms of Racial Discrimination: articles 1 (2) and (3), 5 (d) (i) and (ii), and 6;

(e) Declaration on the Elimination of Discrimination against Women: articles 6 (c) and 8;

(f) Charter of the International Military Tribunal, Nürnberg, article 6;

(g) Convention on the Prevention and Punishment of the Crime of Genocide: article II (e);

(h) Slavery Convention: articles 2 and 3;

(i) Supplementary Convention on the Abolition of Slavery, the Slave Trade and Institutions and Practices Similar to Slavery: articles 1 and 3;

(j) Convention for the Suppression of the Traffic in Persons and of the Exploitation of the Prostitution of Others: articles 1 and 17;

(k) Convention on the Reduction of Statelessness: article 7 (3), (4) and (5) and article 9;

(l) Convention relating to the Status of Stateless Persons: articles 4, 13, 14, 15, 16, 17, 18, 19, 20, 21, 22 (1), 22 (2), 23, 24, 26, 28, 29 (1), 29 (2), 31 and 32;

(m) Convention relating to the Status of Refugees: articles 4, 13, 14, 15, 16, 17, 18, 19, 20, 21, 22 (1), 22 (2), 23, 24, 26, 28, 29 (1), 29 (2), 31, 32, 33 and 34;

(n) Declaration on Territorial Asylum: articles 1, 2 and 3;

(o) Declaration of the Rights of the Child: article 9;

(p) Declaration on Social Progress and Development: articles 1, 8, 14 (b), 17 (a) and (c) and 19 (c);

(q) International Development Strategy for the Second United Nations Development Decade (General Assembly resolution 2626 (XXV)), paragraphs 66, 71 and 75;

(r) General Assembly resolutions 2320 (XXII), 2417 (XXIII) and 3017 (XXVII) concerning the "brain-drain";

(s) General Assembly resolution 2920 (XXVII) on the Exploitation of labour through illicit and clandestine trafficking;

(t) Declaration of the United Nations Conference on the Human Environment, Stockholm, 16 June 1972, principles 15 and 16.

53. Other international instruments in the field of migration and human rights include:

(a) The ILO Convention No. 97 concerning Migra-

tion for Employment (Revised 1949): articles 6, 8 and annex II, articles 10 and 11;<sup>51</sup>

(b) The 1949 ILO Convention on Freedom of Association and Protection of the Right to Organize: article 2;<sup>51</sup>

(c) The UNESCO Convention against Discrimination in Education: article 3 (e);<sup>52</sup>

(d) The 1949 Geneva Convention Relative to the Protection of Civilian Persons in Time of War: article 49;

(e) The European Convention on Human Rights and Fundamental Freedoms;

(f) The Protocol No. 4 to the European Convention on Human Rights: articles 2, 3 and 4;

(g) The European Social Charter, 1961: articles 12 (4), 13 (4), 18 and 19 and appendix;

(h) The Treaty Establishing the European Economic Community: articles 36, 117 and 118;<sup>53</sup>

(i) The American Convention on Human Rights: article 22.

#### *Human rights provisions concerning international migration*

##### *General principles*

54. The right of everyone to leave any country, including one's own, is set forth in paragraph 2 of article 13 of the Universal Declaration of Human Rights, in paragraph 2 of article 12 of the International Covenant on Civil and Political Rights, in articles 2 and 3 of Protocol No. 4 to the European Convention on Human Rights and Fundamental Freedoms and in paragraphs 2 and 3 of article 22 of the American Convention on Human Rights.

55. The inclusion in the Universal Declaration of a general right to leave any country was accepted by the Commission on Human Rights.<sup>54</sup> It rejected a proposal that any reference to such right be deleted on the ground that it would encourage emigration. In the course of the discussion it was recognized that the right to emigrate could not be effective without facilities for immigration and transit on the part of other countries. It was therefore recommended that that corollary be considered as a matter of international interest and that members of the United Nations should co-operate by taking as far as possible the necessary measures to accord such facilities (E/CN.4/57). However, when the Commission adopted the final draft of the article at its third session, it was pointed out that nothing in the article related to a right to immigration, which remained a field regulated by the national legislation of each country (E/CN.4/SR.55).

<sup>51</sup> International Labour Organisation, *Conventions and Recommendations, 1919-1966* (Geneva, 1966).

<sup>52</sup> United Nations Educational, Scientific and Cultural Organization, *Records of the General Conference, Eleventh Session, Resolutions*, section B.I.

<sup>53</sup> United Nations, *Treaty Series*, vol. 296.

<sup>54</sup> *Official Records of the Economic and Social Council, Third Year, Seventh Session, Supplement No. 2*, document E/800.

56. Although several countries expressed misgivings about the inclusion in the Declaration of an unrestricted right to emigrate without any reservations, it was eventually agreed by the Drafting Committee and by the Commission not to include any reservations in article 13, as the Declaration's general article on restrictions (article 29) would afford adequate safeguards for the general prerogatives of the community and the State (E/CN.4/95).

57. An amendment introduced in the Third Committee to make the right subject to the procedure laid down in the laws of each country was not accepted,<sup>55</sup> as it was considered that the national laws should conform to the Declaration and not vice versa, and that the principle of freedom of movement did not prevent States from promulgating laws or ordinances to cope with questions of public order or public health under article 29 of the Declaration.<sup>56</sup>

58. On the other hand, article 12 of the International Covenant on Civil and Political Rights does contain in paragraph 3 a limitation clause to the effect that the rights enunciated in paragraphs 1 and 2 (i.e., freedom of movement and of residence within the territory of a State, and freedom to leave any country, including one's own) may only be subject to restrictions provided by law and necessary to protect "national security, public order (*ordre public*), public health or morals or the rights and freedoms of others and (which) are consistent with the other rights recognized in the present Covenant".

59. Among the restrictions that various representatives in the Commission on Human Rights mentioned as being legitimate were those which might be imposed in a national emergency, in epidemics, for the control of prostitution,<sup>57</sup> on immigrants as a temporary measure, on migrant workers in certain cases or on indigenous population in certain circumstances for their own protection. It was agreed that the right to leave any country could not be claimed in order to escape legal proceedings, such obligations as national service, and the payment of fines, taxes or maintenance allowances. In connexion with the proviso that any restriction should be consistent with the other rights recognized in the Covenant, attention was drawn to the importance of the provisions on non-discrimination in paragraph 1 of article 2 as applied to this article. On the other hand, some members of the Commission regarded the wording of the limitation clause in article 12 of the Covenant as too vague and capable of leading to abuse.<sup>58</sup>

60. Although no general right of immigration exists in any instrument of the United Nations, the right of

<sup>55</sup> *Official Records of the General Assembly, Third Session, Annexes*, agenda item 58, document A/777.

<sup>56</sup> *Ibid.*, *Third Committee*, 120th meeting.

<sup>57</sup> In this connexion, see article 17 of the Convention for the Suppression of the Traffic in Persons and of the Exploitation of the Prostitution of Others.

<sup>58</sup> *Official Records of the General Assembly, Tenth Session, Annexes*, agenda item 28 (part II), document A/2929, chap. VI, paras. 51-60.

everyone to "return" to "his" country was included in paragraph 2 of article 13 of the Universal Declaration of Human Rights. The parallel provision in the Covenant is in paragraph 4 of article 12 according to which "no one shall be arbitrarily deprived of the right to enter his own country". Similar provisions are to be found in Protocol No. 4 of the European Convention on Human Rights (article 3) and in the American Convention on Human Rights (article 22).

61. It will be noted that unlike the Declaration, the Covenant uses the word "enter" instead of "return". This was done in order to include such cases as those of persons born abroad who had never been to the country of their nationality. Earlier drafts of this provision in the Covenant referred to the right of everyone to enter the "country of which he is a national". These last words were eventually replaced in the Commission by "his own country" in order to cover the cases of States where the right of "return" was governed not by rules of nationality but by permanent residence.<sup>58</sup>

62. Though the limitation clause in article 12 of the Covenant does not extend to the provision in paragraph 4, the word "arbitrarily" was added in the Third Committee in order to emphasize that the right to enter one's own country was not absolute. (The draft prepared by the Commission on Human Rights, on the other hand, recognized the possibility of exile provided it was not "arbitrary".) Some members were of the view that this right should not be subject to any restrictions.<sup>59</sup> The word "arbitrarily" was eventually adopted by 29 votes to 20, with 20 abstentions.

63. The whole of article 12 is subject to the general derogation clause contained in article 4 of the Covenant, which authorizes States under certain conditions to adopt measures derogating from their obligations under the Covenant in time of public emergency.

#### *Prohibition of discrimination*

64. The right to leave any country, including one's own, and to return to one's country is recognized to everybody "without distinction of any kind such as race, colour, sex, language, religion, political or other opinion, national or social origin, property, birth or other status" (article 2, para. 1, of the Universal Declaration and of the International Covenant on Civil and Political Rights).

65. In addition, article 5 (d) (ii) of the International Convention on the Elimination of All Forms of Racial Discrimination imposes the obligation upon States parties to guarantee the right of everyone to leave any country, including one's own, and to return to one's country "without distinction as to race, colour, or national or ethnic origin".

66. Under the Declaration on the Elimination of Discrimination against Women, States are also enjoined to adopt all appropriate measures to ensure to women

"the same rights as to men with regard to the law on the movements of persons" (article 6, para. 1 (c)).

#### *Prohibition of expulsion or forced transfers of populations beyond the frontiers of a State*

67. The forced transfer of persons for purposes of the slave trade as well as arbitrary exile are forbidden by articles 4 and 9 of the Universal Declaration of Human Rights, while the arbitrary expulsion of aliens is prohibited under article 13 of the International Covenant on Civil and Political Rights.

68. More specifically, article 6 of the Charter of the International Military Tribunal at Nürnberg classifies as war crimes, *inter alia*, "the deportation to slave labour or for any other purpose of civilian population in occupied territory", and includes in its definition of crimes against humanity the deportation of civilian population before or after the war, in connexion with a war crime against peace. Individual and mass forcible transfers as well as deportations of civilians are also prohibited under the Geneva Convention Relative to the Protection of Civilian Persons in Time of War.

69. Under article II, paragraph (e), of the Genocide Convention, the forcible transfer of children of one group to another group with intent to destroy, in whole or in part, a national, racial or religious group is punishable as genocide. It may be added that no physical destruction is required for the commission of this crime. A forcible transfer of several children—not necessarily on a mass scale—to another group with the purpose of destroying, in whole or in part, the consciousness of the group to which the children belong suffices.

70. The slave trade is specifically outlawed by the Slavery Convention of 1926 (articles 2 and 3) and made a criminal offence by article 3 of the Supplementary Convention of 1956. The traffic in persons for the purpose of prostitution is also outlawed by article 1 of the Convention for the Suppression of the Traffic in Persons and of the Exploitation of the Prostitution of Others and by article 8 of the Declaration on the Elimination of Discrimination against Women.

#### *Special problems that arise in connexion with the right of nationals to leave their own country and to return to it*

##### *Exile and denationalization*

71. The right of every person to leave his country and to return to it is closely linked with the questions of denationalization and of exile.

72. Article 9 of the Universal Declaration stipulates that "no one shall be subjected to arbitrary arrest, detention or exile". When the prohibition of exile was included in the text of article 9 by the Third Committee it was understood that the word "arbitrary" qualified also the term "exile", and an amendment providing for unqualified prohibition of exile was, in fact, rejected.<sup>60</sup>

<sup>59</sup> *Ibid.*, Fourteenth Session, Third Committee, 954th-959th meetings.

<sup>60</sup> *Ibid.*, Third Session, Third Committee, 113th and 114th meetings.

73. The Covenant on Civil and Political Rights does not contain a prohibition of arbitrary exile, but simply stipulates in paragraph 4 of article 12 that "no one shall be arbitrarily deprived of the right to enter his own country": The draft prepared by the Human Rights Commission did contain such an express prohibition,<sup>61</sup> but, after a lengthy discussion in the Third Committee that provision was altered in favour of the present text.<sup>62</sup>

74. Apart from other consequences, the loss of nationality often entails the loss of the right to return to one's country. Arbitrary deprivation of nationality is prohibited under article 15 (2) of the Universal Declaration, while according to article 9 of the Convention on the Reduction of Statelessness (not yet in force), States parties may not deprive "any person or group of persons of their nationality on racial, ethnic, religious or political grounds". This Convention also provides in article 7 (3) that, subject to certain exceptions, departure or residence abroad shall not be regarded as grounds for depriving a national of a Contracting State of his nationality, so as to become stateless.

#### *The "brain-drain"*

75. The accelerated flow of trained personnel from developing to developed countries has been the object of discussion and increasing concern by the General Assembly. At its twenty-seventh session, the General Assembly by resolution 3017 (XXVII) invited the Secretary-General to undertake a study to assess the negative consequences of such outflow for the developing countries and to draft the guidelines for an action programme to be elaborated by the Committee on Science and Technology for Development in order to put an end to and reverse the flow "in conformity with the Universal Declaration of Human Rights".

#### *Migratory labour*

76. If the migration of highly trained personnel may hinder the economic and social development of the developing countries, the migration of foreign workers often leads to problems of exploitation and discrimination both in the method of their recruitment and conditions of transportation and in the treatment they meet within the country of destination.

77. The growing concern of the international community about the abuses to which migrant workers in transit are increasingly subjected led the General Assembly, in resolution 2920 (XXVII) of 15 November 1972, to ask the Commission on Human Rights to consider the question as a matter of priority and to request Governments to take or supervise the application of measures to put an end to discriminatory treatment of migrant workers while urging those Governments which had not yet done so to ratify at

<sup>61</sup> *Ibid.*, Tenth Session, Annexes, agenda item 28 (part II), document A/2929, chap. VI, paras. 58-60.

<sup>62</sup> *Ibid.*, Fourteenth Session, Annexes, agenda item 34, document A/4299, paras. 3-19.

an early date ILO Convention No. 97 concerning Migration for Employment (revised 1949).

#### *Human rights standards concerning the entry and departure of non-citizens and the right of asylum*

78. While the right of non-citizens to leave the country in which they are has been recognized in both the Universal Declaration and the International Covenant on Civil and Political Rights, their right to enter a foreign country, and not to be expelled therefrom, has not received similar attention. However, some countries recognize the right of "return" of non-citizens who are permanent residents. The Treaty Establishing the European Economic Community provides in article 36 for the free movement of workers within the Community.

79. However, the arbitrary expulsion of an alien "lawfully in the territory of a State Party" is forbidden by article 13 of the Covenant, which prescribes that he can be expelled only "in pursuance of a decision reached in accordance with law" and that he shall be allowed, except for reasons of national security, to submit reasons against his expulsion and to have his case reviewed by a competent authority. It will be noted that this provision applies to any alien "lawfully in the territory of a State Party". An amendment to insert the word "established" after "lawfully" during the discussion of the article in the Third Committee was rejected, several members opposing it on the ground that it tended to narrow the scope of the article to a limited group of aliens.<sup>63</sup>

80. Similar provisions against arbitrary expulsion can be found in article 31, paragraph 2, of the Convention Relating to the Status of Stateless Persons, and in article 32, paragraph 2, of the Convention Relating to the Status of Refugees.

81. The Refugee Convention furthermore contains an emphatic provision in article 33 prohibiting *refoulement*, that is, the expulsion or return of a refugee to the frontier or territory where his life or religion would be threatened on account of his race, religion, nationality, membership of a particular social group or political opinion.

82. Convention No. 97 of the International Labour Organisation concerning Migrants for Employment (revised 1949), mentioned in General Assembly resolution 2920 (XXVII), imposes in article 8 restrictions on the right of a State to return to his country of origin a migrant for employment, who has been admitted on a permanent basis and members of his family authorized to accompany or join him, on the grounds that the migrant is unable to follow his occupation by reason of illness contracted or injury sustained subsequent to entry, at least after a maximum of five years from the date of admission has elapsed.

83. The right of everyone "to seek and enjoy in other countries asylum from persecution" is recognized by

<sup>63</sup> *Ibid.*, paras. 20-29.

article 14 of the Universal Declaration except in cases of prosecutions genuinely arising "from non-political crimes or from acts contrary to the purposes and principles of the United Nations".<sup>64</sup> When the draft article was being studied in the Third Committee the words "to enjoy" were added in the first paragraph in order to make it clear that an individual, who had been granted asylum into a country, should continue to benefit from his right of asylum and could not be arbitrarily expelled, though in the view of some members he could be subjected to certain restrictions imposed by the receiving State for reasons of national security or public order.<sup>65</sup>

84. The International Covenants do not contain any provision on the right of asylum. During the discussion of article 13 of the Covenant on Civil and Political Rights several proposals to include this right were discussed and rejected. While the principle of the desirability of States being generous in extending asylum to persecuted individuals was generally accepted, there was deep division concerning the desirability of translating this principle into a positive right.<sup>66</sup>

85. The Declaration on Territorial Asylum adopted by the General Assembly in resolution 2312 (XXII), though mindful of the provisions in article 14 of the Universal Declaration, avoids the use of the word "right" except in paragraph 2 of article 1, when it declares that "the right to seek and to enjoy asylum" may not be invoked by any person suspected of having committed a crime against peace, a war crime or a crime against humanity. The Declaration in its preambular part recognizes that the grant of asylum is a humanitarian act which cannot be regarded as unfriendly by any other State, but further states in articles 1 (1) and (3) that the decision whether to grant asylum is an act of sovereignty of the State concerned.

86. Article 3, paragraph 1, of the Declaration on Territorial Asylum contains a prohibition against rejection at the frontier and against *refoulement* of persons entitled to seek asylum under article 14 of the Universal Declaration, including persons struggling against colonialism. The only exception to this provision is "for overriding reasons of national security or in order to safeguard the population, as in the case of a mass influx of persons" (article 3, para. 2). However, in these cases the State concerned shall consider the possibility of granting to the person concerned an opportunity of going to another country (article 3, para. 3).

87. The Refugee Convention in article 31 contains a provision somewhat related to the concept of asylum

when it lays down that States Parties shall not impose penalties, on account of their illegal entry or presence, upon refugees who come from a territory in which their life or freedom is threatened, provided they present themselves without delay to the authorities and show good cause for their illegal entry or presence. States Parties in such cases can either regularize the status of such persons or must allow them a reasonable time and facilities to obtain admission into another country. The prohibition against *refoulement* contained in article 33 applies also to these cases.

*Rights guaranteed to migrants  
in their country of settlement*

*Civil and political rights*

88. From a reading of the Universal Declaration of Human Rights and of the International Covenant on Civil and Political Rights, and particularly of the non-discrimination clauses in paragraph 1 of article 2 of both instruments, it would appear to follow that the provisions contained therein, with the exception of political rights of the nature specified in article 21 of the Declaration and article 25 of the Covenant, extend to everyone within the territory of a State, including migrants.

*Protection from racial discrimination*

89. Article 6 of the Convention on the Elimination of All Forms of Racial Discrimination imposes on States Parties the obligation of affording to "everyone within their jurisdiction" effective protection and remedies against any acts of racial discrimination contrary to the Convention. Thus, it appears that a migrant is entitled to protection from, and to seek a remedy against, any act of racial discrimination of which he has been a victim, provided that such act cannot be characterized as a "distinction, exclusion, restriction or preference made by the State between citizens and non-citizens" under the reservation clause contained in article 1, paragraph 2, of the Convention.

90. The General Assembly in resolution 2920 (XXVII) of 15 November 1973 requested Governments to take or supervise measures to put an end to discriminatory treatment of migrant workers and to ensure respect for the provisions of the International Convention on the Elimination of All Forms of Racial Discrimination.

*Economic, social and cultural rights*

91. It would appear that the provisions contained in the International Covenant on Economic, Social and Cultural Rights extend to immigrants who are not citizens of the country in which they live with the limitations and provisos laid down, *inter alia*, in articles 1, 2 (3) and 25. It will be recalled that article 2 (3) in particular allows developing countries to decide "to what extent they will guarantee the economic rights recognized in the Covenant to non-nationals".

<sup>64</sup> For a discussion on this article in the drafting committee of the Commission on Human Rights, see E/CN.4/AC.1/SR.36 and 37; and in the Commission, see E/CN.4/SR.56 and 57.

<sup>65</sup> *Official Records of the General Assembly, Third Session, Third Committee, 121st and 122nd meetings.*

<sup>66</sup> *Ibid., Tenth Session, Annexes, agenda item 28 (part II), document A/2929, chap. VI, paras. 65-72.* For a summary of the discussions on the right of asylum which took place in the Commission on Human Rights between 1947 and 1957, see E/CN.4/713 and E/CN.4/738 and Corr.2.

92. Certain economic, social and cultural rights appear to be clearly recognized to immigrants.<sup>67</sup> Thus, the right to equal remuneration for work of equal value is guaranteed to everyone "without distinction of any kind" by article 7 (a) (i) of the Covenant; the right to join trade unions is recognized by articles 8 (1) (a) of the Covenant on Economic, Social and Cultural Rights, 22 of the Covenant on Civil and Political Rights and 23 of the Universal Declaration.<sup>68</sup> The right of all peoples "to live in dignity and freedom and to enjoy the fruits of social progress without distinction as to (*inter alia*) nationality", is set forth in article 1 of the Declaration on Social Progress and Development proclaimed by the General Assembly in resolution 2542 (XXV).

93. On the other hand, it would appear that migrants may not claim to constitute any ethnic, religious or linguistic minority within the meaning of article 27 of the Covenant on Civil and Political Rights. When this article was discussed in the Third Committee it was emphasized by many delegations representing countries of immigration that persons of similar background who entered their territories voluntarily through a gradual process of immigration could not be regarded as minorities and thus entitled to the special provisions of article 27, as this would endanger the national integrity of the receiving States.<sup>69</sup>

*Special measures for the protection of migrant workers*

94. Certain provisions in human rights instruments are specifically directed to the protection of migrant workers. Thus, the ILO Convention concerning Migration for Employment (revised 1949) in article 6 imposes the obligation upon States Parties to accord to immigrants the same treatment as to nationals in respect of: (a) remuneration, allowances and conditions of work; (b) membership of trade unions; (c) accommodation; (d) social security; (e) employment taxes, dues and contributions; and (f) legal proceedings relating to matters referred to in the Convention.

95. Annex II to this Convention "concerning Recruitment, Placing and Conditions of Migrants for Employment Recruited under Government Sponsored

Arrangements for Group Transfer" contains provisions designed to assist the migrant in finding alternative employment, "which does not prejudice national workers", if the employment for which he was recruited has been found to be inadequate (article 10). In the event of the migrant being also a refugee and becoming redundant, efforts must be made to find him alternative employment not prejudicial to national workers and to ensure his maintenance in the meantime (article 11).

96. It may be recalled that the Declaration on Social Progress and Development in article 19 (c) called on Governments to provide social welfare services for migrant workers and their families in conformity with the provisions of ILO Convention No. 97, and that the General Assembly in resolution 2920 (XXVII) of 15 November 1972 urged Governments which had not yet done so to give high priority to the ratification of this Convention in the context of their efforts to eliminate illicit trafficking in foreign labour. The same resolution invited the International Labour Organisation to strengthen the international machinery for the protection of migrant workers.<sup>70</sup>

*Special measures concerning stateless persons and refugees*

97. The Conventions relating to the Status of Stateless Persons and of Refugees contain provisions assimilating stateless persons and refugees to nationals in the enjoyment of certain rights (articles 4, 14, 16, 20, 22 (1), 23, 24 and 29 (1) of both Conventions) or according them the most favourable treatment granted to nationals of a foreign country (see articles 15 and 17 of the Refugee Convention), while other provisions accord refugees and stateless persons no less favourable treatment than that accorded to other aliens (articles 13, 18, 19, 21, 22 (2), 26 and 29 (2) of both Conventions and articles 15 and 17 (1) of the Convention on Stateless Persons). The Conventions also contain provisions to facilitate naturalization (articles 32 of the Convention on Stateless Persons and 34 of the Refugee Convention) and the travel (article 28 of both Conventions) of refugees and stateless persons.

<sup>67</sup> The Treaty of Rome setting up the European Economic Community provides in article 36, paragraph 2, for the abolition of any discrimination based on nationality between workers of the Member States as concerns employment, remuneration and other working conditions. The appendix to the European Social Charter of 1961 declares that the provisions of the Charter extend to foreigners who are nationals of other Contracting Parties lawfully resident or working regularly within the territory of the Contracting Party concerned. Furthermore, articles 12 (4) and 13 (4) of the Charter impose concrete obligations on States Parties to extend to the nationals of the other Contracting Parties certain social security benefits, including medical assistance in case of want.

<sup>68</sup> See also article 2 of the ILO Convention on Freedom of Association and Protection of the Right to Organize and article 6 (b) of ILO Convention No. 97 concerning Migration for Employment.

<sup>69</sup> Official Records of the General Assembly, Sixteenth Session, Annexes, agenda item 35, document A/5000, paras. 119-124.

<sup>70</sup> On the rights of migrant workers see, *inter alia*, the following ILO resolutions and instruments: the Convention concerning Conditions of Employment of Plantation Workers, 1958; recommendation No. 86 concerning Migration for Employment (revised 1949); recommendation No. 100 concerning the Protection of Migrant Workers in Underdeveloped Countries and Territories, 1955; resolution V concerning action by the International Labour Organisation for Migrant Workers, 1967; resolution VIII concerning Trade Union Rights and their Relation to Civil Liberties, 1970 (in particular, operative paragraph 8 inviting "the Governing Body to extend and expand its efforts to eliminate the discriminatory practices on the basis of race, colour, sex, religion, nationality, political and trade union opinion which still exist in several countries, including countries and territories under a colonial régime or foreign domination in any form"); resolution III concerning ILO Action for Promoting the Equality of Migrant Workers in All Social and Labour Matters, 1971; and resolution IV concerning Conditions and Equality of Treatment of Migrant Workers, 1972 (referred to also in General Assembly resolution 2920 (XXVII)).

*Human rights provisions concerning internal migration and the movement of persons within the frontiers of a State*

*General principles*

98. The right to freedom of movement and residence within the territory of a state is proclaimed in article 13 (1) of the Universal Declaration of Human Rights and in article 12 (1) of the International Covenant on Civil and Political Rights.

99. This right is recognized by the Declaration to "everyone" and is subject only to the general limitations laid down in article 29.

100. The right to liberty of movement and freedom to choose one's residence belongs, according to paragraph 1 of article 12 of the Covenant, to "everyone lawfully within the territory of a State", subject to the limitation clause in paragraph 3.<sup>71</sup> Among the restrictions consistent with the provisions of this paragraph can be mentioned the detention of a person in consequence of a lawful order of a court, the limitation on the freedom of movement of a person resulting from conditional release from detention, national service, any service exacted in cases of emergency or calamity or any work or service forming part of normal civil obligations (article 8 (3) (c) (i) (ii) (iii) and (iv) of the Covenant) as well as the lawful arrest and detention of a person under the conditions set down in article 9.

101. The right to freedom of movement and of residence can be derogated in times of public emergency under the provisions of article 4 of the Covenant subject to the conditions laid down therein.

*Respective rights of nationals and aliens concerning freedom of movement in the territory of a State*

102. The right to freedom of movement and of residence is recognized in the Universal Declaration to "everyone" without, according to article 2, "distinction of any kind".

103. The provisions of paragraph 1 of article 12 of the Covenant extend to "everyone lawfully within the territory of a State" and are subject to the general non-discrimination clause contained in article 2, paragraph 1, of the Covenant. Thus, it would appear that restrictions on the freedom of movement of aliens would ordinarily be contrary to the Covenant. However, it would appear that a State has the right to limit the freedom of movement of aliens in times of public emergency, since the non-discrimination provision in article 4 is couched in more restrictive terms than article 2 and does not include nationality in the exhaustive enumeration of the grounds of discrimination prohibited under it.

104. Parties to the International Convention on the Elimination of All Forms of Racial Discrimination have the obligation under article 5 (d) (i) to guarantee the enjoyment of the right to freedom of movement and of

residence within the border of the State to everybody without distinction as to race, colour or national or ethnic origin. This provision, however, has to be read in the context of the exemption clause in article 1 (2) to the effect that the Convention shall not apply to distinctions made by a State between citizens and non-citizens.

105. Article 26 of the Convention on the Status of Stateless Persons and of the Refugee Convention provide that stateless persons and refugees shall enjoy freedom of movement and of residence "subject to any regulations applicable to aliens generally in the same circumstances".

*Prohibition of forced transfers of population within the territory of a State*

106. Most of the provisions prohibiting forced transfers of persons beyond the frontiers of a State also prohibit forced transfers within its borders. Thus, article 6 of the Nürnberg Charter, mentioned above, prohibits the deportation of civilian population, while the forcible transfer of children of one group to another group, punishable under article II (e) of the Genocide Convention, can take effect within the borders of a State.

107. Apart from the prohibition of the slave trade already referred to, certain institutions and practices akin to slavery are outlawed by article 1 of the Supplementary Convention on the Abolition of Slavery, the Slave Trade and Institutions and Practices Similar to Slavery, including the transfer of a woman by her husband, his family or clan to another person for value received, the institution or practice by which a woman is liable on her husband's death to be inherited by another person and the transfer or deliverance of children or young persons under 18 years of age by their parents or guardians to another person for the purpose of the exploitation of the child or of his labour. The traffic of children "in any form" is prohibited by article 9 of the Declaration of the Rights of the Child.

*Measures to promote rural development and the planning of urban growth*

108. The United Nations has of late increasingly turned its attention to the economic, social and environmental problems caused by the mass movements of persons from rural into urban areas.

109. Thus, the Declaration on Social Progress and Development recognizes the need for planned regional development, taking into account the diversity of needs between urban and rural areas (article 8 and 14 (b)), the importance of maintaining a proper balance between urban and rural development and of adopting measures to overcome the adverse social effects resulting from urban development and industrialization (article 17 (a)) as well as the requirement for comprehensive rural development schemes to raise the levels of living of the rural population and to facilitate urban-rural relationships and population distribution (article 17 (c)).

<sup>71</sup> See paragraphs 58 and 59 above.

110. The need to emphasize rural employment in developing countries and to remedy the ills of unplanned urbanization is emphasized also in the International Development Strategy for the Second United Nations Development Decade adopted by the General Assembly in resolution 2626 (XXV) of 24 October 1970 (paras. 66, 71 and 75).

111. The Declaration of the United Nations Conference on the Human Environment adopted in Stockholm on 16 June 1972 stated in principle 15: "Planning must be applied to human settlements and urbanization with a view to avoiding adverse effects on

the environment and obtaining maximum social, economic and environmental benefits for all. In this respect profits which are designed for colonialist and racist domination must be abandoned." In principle 16, the Conference expressed its common conviction that "demographic policies, which are without prejudice to basic human rights and which are deemed appropriate by Governments concerned, should be applied in those regions where the rate of population growth or excessive population concentrations are likely to have adverse effects on the environment or development, or where low population density may prevent improvement of the human environment and impede development".

## THE IMPACT OF FERTILITY ON HUMAN RIGHTS \*

Francis X. Murphy \*\*

1. In an era of mounting concern for the potentially disastrous consequences of an exponential increase in human numbers, the right of individual human beings to decide freely and responsibly the questions of procreation and family size as a personal prerogative must be thoroughly evaluated. Individual rights in all aspects of fertility have to be balanced against the needs of the larger community—family, State and ultimately the world. General resistance to family planning policies as a requirement of national development is rapidly disappearing. Thus, the concern of this Symposium on Population and Human Rights should be centred on the implementation of rights that relate more directly to human reproduction and the effect that the regulation of fertility has on the exercise of freedom and responsibility.

2. In the pursuit of this objective, it is necessary to concentrate on those rights that can be considered in the context of current and projected population programmes. The motivation behind individual decisions in this respect depends greatly upon the cultural, legal, moral, political and economic factors affecting peoples' attitudes. Of equal relevance is the understanding and use of the methods of fertility regulation available. This paper concentrates on what can be termed "the humanitarian aspects of fertility control", in the effort to propose concrete measures for the implementation of the human rights and obligations whose pursuit is a principal objective of the Population Year 1974.

### FERTILITY CONTROL

3. The development of principles by United Nations bodies concerned with the confrontation of fertility by the contemporary world has reached a stage in which it is conceded that there is a legitimate variety of goals in population policies. Some countries are satisfied with current levels of population; others are seeking increases; and still others are strenuously working to reduce fertility levels in the hope of achieving social and economic development. While some States are concerned more with problems of sterility and sub-fertility, the majority appear most anxious to control

fertility levels and to persuade Governments and individuals, particularly in the developed areas, to cut back on over-use or wastage of natural resources and to reduce human reproduction in keeping with world needs.<sup>1</sup>

4. Several fundamental problems arise with the acceptance by the United Nations of the principle that individuals have the right to determine the number and spacing of their children freely and responsibly,<sup>2</sup> such as those concerning where this right is lodged; the way in which this right is to be realized, particularly in areas where the common good of a country or a people appears to be threatened by over-population; whether the Government has the right to establish fertility limits for individuals based upon the common good; and, if so, the way in which it implements such a policy in the face of contrary traditions and beliefs.

5. The United Nations approach to the problem of fertility is based upon the Universal Declaration of Human Rights, which asserts that men and women of full age "have the right to marry and found a family".<sup>3</sup> This fundamental prerogative is clarified in a series of statements locating relevant human rights and responsibilities in the family, which, "as the basic unit of society and the natural environment for the growth and well-being of all its members, especially children and youth, should be assisted and protected".<sup>4</sup> This principle has been considerably modified by the gradual extension of its provisions to include the right of individuals to determine freely and responsibly the number and spacing of their offspring.<sup>5</sup>

6. The possible conflict between the exercise of freedom to procreate and the assumption of full

<sup>1</sup> "Report of the Secretary-General on the draft world population plan of action" (E/CN.9/292), p. 12.

<sup>2</sup> General Assembly resolution 2211 (XXI) of 17 December 1966; *Final Act of the International Conference on Human Rights*, Teheran, April-May 1968 (United Nations publication, Sales No. E.68.XIV.2), resolution XVIII; General Assembly resolution 2716 (XXIV) of 15 December 1970, sect. II C, para. 4.

<sup>3</sup> Universal Declaration of Human Rights, art. 16; International Covenant on Civil and Political Rights, art. 23; Covenant on Economic, Social and Cultural Rights, art. 10; General Assembly resolution 2018 (XX) of 1 November 1965.

<sup>4</sup> Declaration on the Rights of the Child, principles 6 and 7; General Assembly resolution 1386 (XIV) of 20 November 1959.

<sup>5</sup> Declaration on Social Progress and Development: General Assembly resolution 2542 (XXIV) of 11 December 1969, arts. 4 and 22(b); General Assembly resolution 2716 (XXIV) of 15 December 1970, sect. II C, para. 4.

\* The original text of this paper (E/CONF.60/SYM.IV/4) was submitted to the Symposium on Population and Human Rights, Amsterdam, 21-29 January 1974.

\*\* Professor of the History of Moral Theology; Fellow at the Woodrow Wilson International Center for Scholars, Washington, D.C.

responsibility for the care and upbringing of offspring is to be settled in favour of the child.<sup>6</sup> The details of the latter's rights are given full attention in United Nations<sup>6</sup> instruments. They include the right of the child to be brought up in an "atmosphere of affection, and of moral and material security" based on the child's need for love and understanding. In turn, this requires that the child be given the possibility of growth and development in health, the enjoyment of adequate nutrition, housing, recreation and medical services in the care of its parents.<sup>7</sup> Provision is also made for an education on the basis of equal opportunity to develop its abilities and judgement, its sense of moral and social responsibility to become a useful member of society, protected from neglect, cruelty and exploitation.<sup>8</sup>

7. These provisions for the rights of the child indicate that parents should not have a child when they are not capable of giving it the essential care to which it is entitled. This reflection is crucial to the problem of population control, for it means that both in affluent societies and in deprived areas, no one should conceive and bring a child into the world without the possibility of giving it the essential love and care that will enable it to develop into a mature and responsible individual. It is within the context of these considerations that Government is justified in setting out population policies; and, in the attempt, to persuade people not to beget more children when their own or the country's economic and social conditions make it difficult or close to impossible to provide them with the factors necessary for the exercise of human dignity.

#### MARRIAGE AND PARENTHOOD

8. Considerable diversity exists in the concept of the family. This fact has to be taken into consideration in any attempt to clarify human rights in their relation to fertility. In many societies, *de facto* unions are far more numerous than formal marriages. A large proportion of the female population enters into more-or-less permanent consensual unions or casual "visiting" arrangements in which childbearing is accepted and begins early.<sup>9</sup> This phenomenon is prevalent in many parts of the developing world, and is not rare in vast urban slum areas. In more economically developed societies, single women are demanding the right to parenthood. Both the impermanence of casual marital arrangements and the independence of the unmarried mother challenge the obligation of responsibility in childbearing enunciated in the United Nations instru-

<sup>8</sup> General Assembly resolution 1386 (XIV) of 20 November 1959, Declaration on the Rights of the Child, principles 9 and 10.

<sup>9</sup> United Nations Secretariat, Centre for Social Development and Humanitarian Affairs, "Women's rights and fertility", *Population Debate*, vol. II, part seven, para. 40.

ments clarifying the rights of the child. Thus, a symposium on population and human rights could properly suggest guidance for Governments faced with these phenomena as they affect national and international population policies. Provision for the amelioration of laws concerning illegitimacy; for the suppression of betrothal before the age of puberty, as well as of child marriages; and recommendations concerning polygamy are already contained in United Nations instruments and proposals.<sup>10</sup> Further reflection concerned with the development of the principle of freedom and responsibility in begetting offspring in relation to the rights of women and of men still appears to be a desideratum.

9. The principle of responsibility involves both parents in the obligation to provide factors essential to the child's well-being. In most societies, however, the impact of this obligation devolves more directly on the woman whose physical involvement in bearing the child, and in caring for its immediate wants and needs during infancy and childhood, is substantive. Although the man's desire for offspring and his affection for the child constitute a positive and powerful factor, his involvement is almost always contributory, rather than essential, to the immediate care and welfare of the new human being.<sup>11</sup> In the clarification of women's rights recognized in United Nations instruments, the equality of the wife with the husband is explicitly asserted.<sup>12</sup> This recognition contradicts ancient and traditional customs, whereby male domination prevailed in all decisions affecting the family, despite the substantive part played by the woman in childbearing and in her contribution to the domestic economy. But the exercise of this equality is still far from achieved. As its implementation is obviously connected with fertility control, it is an essential factor in the problems being confronted by this Symposium.

10. In most developing countries, the "large-family syndrome" still plays a crucial role in the population increase and has its roots both in a strong instinctual desire to beget a large progeny and in the fear of being abandoned in old age. In the past, this tendency was related to a high rate of infant mortality. While this latter danger has now been substantially reduced, there is the correlative fact that men and women living in deprived economic and social conditions find achievement in the begetting of a large family. Usually, this satisfaction is sanctioned by custom and religious belief.

The conflict of rights and obligations involved in this situation is the most widespread and difficult of all the problems faced in fertility-control policies.

#### FERTILITY CONTROL PROGRAMMES

11. What now appears evident is that legislation and propaganda efforts by Governments or voluntary agencies do not change ingrained custom, particularly where it is buttressed by ancient tradition, religious beliefs, and clan, tribal or national aspirations. Planned parenthood programmes, while listened to politely and understood in their basic applicability, are simply ignored by people who feel that their privacy is being invaded. In the Buddhist, Hindu and Muslim cultures, as well as in the more fundamentalist Christian churches, there is still a general preference for large families and a strong suspicion that efforts to control conception are an invasion of family prerogatives designed to deprive the man of his virility and the woman of her fecundity.<sup>13</sup>

12. Similarly, in developing societies more generally, sexual behaviour is not considered a matter for discussion; and early marriage is encouraged as part of an ethic that looks to male and female fulfilment in offspring. Here, the experience of recent decades indicates that only a most sensitive approach to the cultural values motivating people's family structures and reproductive *mores* has any chance of success.<sup>14</sup> Where resistance to birth-control practices exists, it cannot always be categorized on an *a priori* basis. The assumption that a failure to accept family planning denotes the absence of rational behaviour is frequently not valid. The gains in economic and social well-being associated with a smaller family by birth-control proponents may not appeal to individuals or groups who feel that the advantages of a large family outweigh all such considerations. And it is possible that within the context of a particular region or country, large families are, in fact, advantageous.<sup>15</sup>

#### "CONSCIENTIZATION"

13. In pursuit of the human rights aspect of fertility control, little certain knowledge exists concerning the socio-cultural factors that affect peoples' attitudes towards the planning or control of births.<sup>16</sup> Nevertheless, the contention of sociologists that only when a threshold of modest affluence is reached does a society's birth rate go down, can be accepted as a given fact, even though there is no consensus on the specific reasons for this phenomenon.<sup>17</sup> An effective fertility-control

programme must make every effort to co-ordinate educative efforts with immediate steps towards social and economic uplift at the lowest levels. This process can be called "conscientization". It signifies a method of making people politically conscious through the very means with which they are taught the elements of self-expression, hygienic and nutritional values and self-help in ameliorating local living and working conditions.

14. In the encouragement of this type of human uplift, the Population Year 1974 can offer a concrete hope towards the solution of present population problems. Governments should be encouraged to enlist the aid of agencies of the United Nations and other organizations geared towards research and pragmatic programmes in this endeavour. But they should also take into account the services of voluntary agencies and institutions that reach the people on a local level and that can assist in the gradual shift of their values through both educational and practical services, and through discovery of leadership qualities among local people which can be encouraged and adapted in accord with a reasonable fertility ethos. Here, women's organizations and religious and cultural institutions can play a decisive part, without involving Governments in the direct support of any of these associations.<sup>18</sup>

15. In accord with United Nations instruments, the rights of women to full equality in all spheres of human interests are being gradually acknowledged. Likewise, in almost all national constitutions there is a guarantee of freedom of belief and of religious or cultural affiliation. As these associations have the betterment of people's lives as a principal goal, their involvement in the programme for an effective approach to a just social and economic order should be encouraged.

16. During the past three decades, many of these religious and cultural associations have held local and international conferences devoted to development programmes. They have called upon Governments to direct full attention to the solution of the economic and political problems hampering the uplift of the poor and under-privileged. Thus, they have indicated not merely an interest but an obligation on their part to get involved; and many such associations are actually working on the ground level through inner-city movements, mission activities, and educational, nutritional and medical programmes throughout the developing world.<sup>19</sup>

17. In the discussion of the programmes for action for the Population Year 1974, a specific challenge should be directed to these cultural and religious organizations to have them become thoroughly involved in providing motivation and in clarifying values for the

and Moral Responsibility (Washington, D.C., Public Affairs Press, 1973), pp. 233-251.

<sup>18</sup> See *Measures, Policies and Programmes Affecting Fertility*, loc. cit., pp. 73-78.

<sup>19</sup> See Richard M. Fagley, *The Population Explosion and Christian Responsibility* (New York, Oxford University Press, 1960); Joseph Gremillion, *The Other Dialogue* (New York, Doubleday, 1965).

<sup>16</sup> *Ibid.*, p. 134.

<sup>17</sup> See Philip M. Hauser, "Population criteria in foreign aid programs", in J. Philip Wogaman, ed., *The Population Crisis*

solution of the problems related to fertility control on the level where it originates and where they can be most effective. In view of the clear and evident danger presented by the current world crisis, not merely of a dangerous population surplus, but of the depletion of world resources, the question may be asked if these ethically committed organizations can prove effective; if they can bring home to their members the need for change in attitudes towards the use of life resources, as well as in their reproductive habits.

18. What is generally agreed now is that in the literature on family planning there is full acknowledgement of the need to take socio-cultural factors into account in formulating family planning programmes. But most studies on knowledge, attitudes and practices have not produced hard, factual information with reference to the reasons that populations do not approve of, or practise, family planning.<sup>20</sup> In the challenge placed before them, cultural and religious organizations should be asked for assistance in gathering this information and for aid in utilizing it to offset traditions and taboos whose continuation constitutes a detriment to the solution of the population surplus.<sup>21</sup>

19. In most developing areas, one of the greatest difficulties encountered is in trying to persuade the individual—and keeping him or her persuaded—that systematic family planning is worth all the trouble. The motivation needed to achieve this persuasion cannot be supplied merely by setting up clinics and offering inducements, monetary or otherwise. It necessitates a massive and sustained campaign of education, information and personal persuasive efforts through local leadership and example. It is here that the cultural and religious organizations can be most effective.

#### INFORMATION AND EDUCATION

20. The dissemination of information concerning family planning through mass media, from television and transistor radio to the newspaper and school texts, involves several problems. While there is little objection to the spread of information concerning both the need for family planning as in keeping with human dignity and the right to determine the number and spacing of children, the projection of specific technical information can and does run into opposition. These are those

<sup>20</sup> See *Measures, Policies and Programmes Affecting Fertility*, loc. cit., pp. 11-15 and foot-note 11.

<sup>21</sup> A change of attitude in the Catholic Church is crucial in this respect. In 1965, Vatican Council II acknowledged the right of parents to "decide the number of children they should have" (Pastoral Constitution, *Gaudium et Spes*, paras. 50 and 87). The Encyclical, *Populorum progressio* (1967), acknowledged the need for population control (para. 37). Although the Encyclical, *Humanae vitae* (1968), confused the issue by condemning the use of artificial contraceptives, that document stressed the obligation of responsible parenthood and population control (para. 10). See A. McCormack, *The Population Problem* (New York, 1970). Most other Christian churches favour both responsible parenthood and population control. While the oriental religious groups are, for the most part, indifferent to methods, they incline towards reserve in discussion of such matters and generally favour large families.

people who consider such matters to be of a delicate moral texture not to be made the subject of public or general discussion. Of greater importance, perhaps, is protection of the audience from misconceptions or false appreciation of the physiological aspect of the complicated matters being discussed in fertility control. Also of considerable importance is the protection of children from exposure to information that they are not mature enough to appreciate.

21. The curiosity quotient of children is usually much higher than their parents realize; thus, there is great probability that children are discussing sexual aspects of family planning long before their elders are aware of the fact. This matter, it would seem, is an area for consideration by a symposium such as the present one, in an attempt to balance the right of parents to control the type of education they desire for their children against the children's need to know, in keeping with the interests of their developing minds and bodies, and the information being discussed by their peers.

22. A further extension of this problem is the inclusion of sex education and attitudes towards family planning in school curricula, and the consequent possible conflict of rights between the prerogatives of parents and the policies of the State as the guardian of the social well-being of society. Lastly, the question of making available to minors sex education and information about contraceptive methods, without the knowledge of their parents, has become a delicate issue in the field of human rights. The question may be asked whether such a programme would be looked upon by parents as a threat to the moral guidance they must exercise for the spiritual and psychological well-being of their offspring and whether the programme might possibly offend against the clause of the United Nations resolution calling for protection of children and minors from corruption.<sup>22</sup>

23. The right to exercise freedom and responsibility in spacing and determining the number of offspring includes the necessary information and education to be able to pursue this prerogative. It rules out coercion of any type on the part of Government, particularly the attempt to mislead people having large families into submitting to sterilization or abortion procedures without their understanding the meaning of such interventions. Persuasive means involving educative advertising, direct monetary or tax or other material or cultural advantages are legitimate provided they are properly understood by the populace and are not directly discriminatory against the poor or particular sectors of society.

<sup>22</sup> See Universal Declaration of Human Rights, art. 26; International Covenant on Civil and Political Rights, art. 18, para. 4; Declaration on the Rights of the Child, principle 7; General Assembly resolution 1386 (XIV) of 20 November 1959. No attempt has been made to reconcile the difficulties between the right of parents over against the right of the State to determine the basic information needed for sex education and family planning. See *Official Records of the General Assembly, Twenty-fourth Session, Third Committee, 1682nd meeting*, pp. 173-175.

In United Nations instruments, such discrimination has been made the equivalent of a type of genocide.<sup>23</sup>

24. While the right to know all that is actually understood about fertility control and the means for its actualization is proper to all human beings, and particularly to those of mature age, the deficiencies of the educational process in most societies, and particularly in deprived areas, along with the reluctance of men, more generally, to allow themselves to be approached about such matters, indicate that the most effective procedures are those which attempt to instruct the younger generation of mothers, and through them, the older women.<sup>24</sup>

25. One achievement of Population Year 1974 should be the encouragement of women's rights movements, both in the economically advanced societies and in the developing areas, to undertake a vigorous effort to further the "conscientization" of women with respect to their basic dignity and the power they should wield in the decision-making processes of the economic, social

<sup>23</sup> Convention on the Prevention and Punishment of the Crime of Genocide, art. 2, para. (d). See "Report of the Ad Hoc Working Group of Experts Established under Resolution 2 (XXIII) of the Commission on Human Rights" (E/CN.4/984/Add.18), paras. 29-30. See Edward L. Long, Jr., "Toward a moral critique of governmental coercion", in J. Philip Wogaman, *op. cit.*, pp. 158-185; Arthur Dyck, "Population policies and ethical acceptability", in *Rapid Population Growth: Some Consequences and Public Policy Implications*, prepared by a study committee of the Office of the Foreign Secretary, National Academy of Sciences (Baltimore, Johns Hopkins Press, 1971).

<sup>24</sup> See *Measures, Policies and Programmes Affecting Fertility*, *loc. cit.*, pp. 142-143.

and political order.<sup>25</sup> This does not mean that effort should not be made to enlist the man of the family, particularly in rural and backward areas, who shares an equal burden in achieving its well-being. In practical life, it is usually much easier to effect family and cultural changes such as these through word-of-mouth exchanges among women rather than among men.

26. In the final analysis, the vindication of women's rights should inspire the emancipated woman to a new and vigorous approach to the solution of the world's demographic problems by turning full attention to the essential role that can be played by women, especially in peasant and emerging societies. This will best be achieved by a consistent effort at extending family-support services throughout deprived areas, beginning with hygienic and nutritional education and advancing to a full round of health concerns whose final goal will be the demonstration that fertility control and small family units are the pathway to development. What is essential is that the rights to responsible parenthood be recognized at the ground level, and that the obligations involved in fertility-control programmes be seen as a function of the whole society, rather than as the result of imposition by Government from above.

<sup>25</sup> In a speech on "Population, nutrition and the role of women", delivered at the Conference on World Food and Population Problems (New York, 4 April 1973), Richard M. Fagley insisted that not only do village women play the basic role in the domestic economy, particularly with respect to nutrition, but they are the key to the physical and mental health of the pre-school child, the human capital of the future. Although she is outside the market economy, her contribution of food and clothing is crucial to family survival.

## WOMEN'S RIGHTS AND FERTILITY\*

*United Nations Secretariat\*\**

### WOMEN'S RIGHTS FROM A DEMOGRAPHIC AND HUMAN RIGHTS PERSPECTIVE

1. The United Nations in its Charter and in the Universal Declaration of Human Rights proclaimed its faith in the dignity and worth of the human person and in the equal rights of men and women. All Member States have pledged themselves towards this end. More recent declarations and numerous resolutions have called for equality between men and women in all areas of law, political life, education, employment, and marriage and the family (E/CN.6/552). Moving beyond the concept of legal status alone, the Declaration on the Elimination of Discrimination Against Women, for example, demanded the eradication of prejudice against women and the abolition of all customs, regulations and practices in daily life that are based on the idea of the inferiority of women or that serve to discriminate against them (General Assembly resolution 2263 (XXII), articles 2 and 3).

2. These comprehensive goals are relevant not only to the expansion and protection of basic human rights, but to the analysis of the association between various aspects of the status of women and demographic patterns of fertility, mortality and migration. Fertility, and the social processes associated with it, are of special importance in this regard. The status of women may be seen as both a determinant and a consequence of variations in reproductive behaviour. A woman's health, educational opportunities, employment, political rights and role in marriage and the family all affect, and in turn are affected by, the timing and number of her children and by her knowledge of how to plan them. The impact of birth planning on the individual woman's potential for personal autonomy and for participation in all sectors of society—that is, the human rights aspect of the relationship—is clearly as important as the question of the impact on fertility of improvements in her status, which may be of greater interest from the demographic point of view.

3. In this paper, the status of women in public and private life is measured primarily by the number of

years of their schooling, by their representation in the paid labour force as shown in censuses and surveys, by their integration in major areas of political decision-making, and by their age at marriage and rights and obligations within the family, in so far as these can be determined. These indicators are imperfect, however, especially in the area of employment where labour force statistics often exclude large numbers of female agricultural labourers or other unpaid workers who nevertheless participate actively in the process of production or provide essential services upon which production depends.

### THE RIGHT TO DETERMINE FREELY AND RESPONSIBLY THE NUMBER AND SPACING OF ONE'S CHILDREN

4. In 1966, the United Nations proclaimed for the first time that "the size of the family should be the free choice of each individual family" (General Assembly resolution 2211 (XXI)). The International Conference on Human Rights, in 1968, declared more broadly that couples have a basic human right to decide freely and responsibly on the number and spacing of their children and a right to adequate education and information in this respect.<sup>1</sup> By 1969, the concept had evolved to include the right to knowledge and the means to space and limit births (General Assembly resolution 2542 (XXIV), article 22), and it will continue to evolve as individual and family rights in this area are further elaborated.

5. A number of legal, economic, social and cultural factors, however, constrain women from fully exercising the right to plan births. Such constraints include, for example, legislative restrictions on access to relevant education, information, advice and services;<sup>2</sup> inadequate family planning programmes that leave many women—especially poor and rural women—without knowledge of the possibility or the means to regulate fertility safely

\* This paper was submitted to the Symposium on Population and the Family, Honolulu, 6-15 August 1973, as E/CONF.60/BP/11; and to the Symposium on Population and Human Rights, Amsterdam, 21-29 January 1974, as E/CONF.60/BP/11/Rev.1.

\*\* Department of Economic and Social Affairs, Centre for Social Development and Humanitarian Affairs.

<sup>2</sup> *Measures, Policies and Programmes Affecting Fertility, with Particular Reference to National Family Planning Programmes* (United Nations publication, Sales No. E.72.XIII.2), pp. 39-49; World Health Organization, "Abortion law: a survey of current world legislation", in *International Digest of Health Legislation*, vol. 21, No. 3 (1970), pp. 437-512; and Luke T. Lee and Arthur Larson, eds., *Population and the Law* (Durham, N.C., Rule of Law Press, 1971).

and effectively;<sup>3</sup> cultural definitions of woman's primary role as sexual partner, homemaker and breeder of children rather than as full participant in the social and economic life of her community; lack of alternative roles for women outside the home; and patterns of male dominance within the family, including hostility to the use of female contraceptive methods and to the independent rights of the woman, among others.

6. What is the impact on the individual woman of her ability to plan births? Certainly the knowledge alone of the possibility and means of doing so gives women the power to shape their lives in ways undreamed of by those who have never questioned the inevitability of their childbearing or who have resorted in desperation to cumbersome, ineffective and often dangerous methods to stop unwanted births. Birth planning in this respect is an essential ingredient of health<sup>4</sup> and human dignity. And when the power to space and limit pregnancies is translated into an actual decision to do so, the impact on women's status may be dramatic. Disaggregated into its components of the ability to delay the first birth, to space births several years apart, to stop childbearing earlier in the life cycle and to limit the total number of births (or to have no children), each aspect of birth planning may be examined separately for its effect on the woman's health, on the health of her children, and on the exercise of her economic, social and political rights in the society and in the family.

#### THE RIGHT TO AN EDUCATION

7. According to the Universal Declaration of Human Rights (General Assembly resolution 217 A (III), article 26), everyone has the right to an education. In the Declaration on the Elimination of Discrimination Against Women (General Assembly resolution 2263 (XXII), article 9), among other documents, girls and women, married or unmarried, are to be assured equal rights with men in education at all levels, including study in educational institutions of all types, the same choice of curricula, and equal access to scholarships and other financial support.<sup>5</sup>

8. Equal education has proved to be an elusive goal, however, even in countries where equality under the law is guaranteed. Illiteracy rates in most countries are much higher among women than among men, although the situation is improving.<sup>6</sup> Females are less than half

<sup>3</sup> International Planned Parenthood Federation, *Family Planning in Five Continents* (London, 1972); Dorothy Nortman, "Population and family planning: a factbook", in *Reports on Population/Family Planning*, No. 2, 4th ed. (New York, The Population Council, 1972).

<sup>4</sup> World Health Organization, *Health Aspects of Family Planning*, Technical Report Series No. 442 (Geneva, 1970); International Planned Parenthood Federation, "The relationship between family size and maternal and child health", Working Paper No. 5, London, July 1970; Abdel R. Omran, *The Health Theme in Family Planning*, monograph 16 (Chapel Hill, N.C., Carolina Population Center, 1971).

<sup>5</sup> United Nations Educational, Scientific and Cultural Organization Convention and Recommendation Against Discrimination in Education, 1960.

<sup>6</sup> On average, females aged 15 and over were about 54 per cent as likely as males to be literate in the countries of Africa

of the school population in most countries and their proportions decline rapidly at the highest levels of training.<sup>7</sup> Within educational institutions, certain fields of study are often strongly sex-typed as appropriate for females only or males only, although the degree of sex-typing varies considerably between countries. In many areas, the relative under-representation of girls and women in schools is compounded by an over-all scarcity of educational resources, placing them at an even greater competitive disadvantage.<sup>8</sup> The scarcity is often greatest where population pressures are most acute.

9. One may ask what effect the ability to determine the number and spacing of one's children has on the exercise of woman's right to an education and to equal treatment in the schools at all levels.

10. Delaying the onset of childbearing, either through delaying entry into marriage or *de facto* unions or by postponing the first birth within marriage, is the most relevant aspect of fertility regulation in this regard. Postponing the first birth should have the greatest impact on a woman's opportunities for vocational training or for secondary, college or university education in those countries or among socio-economic groups in which she had a high probability of pursuing an education beyond the normal first years of childbearing to begin with,<sup>9</sup> and in which the birth of a child would effectively limit her chances of staying in school.<sup>10</sup> Where few girls receive higher education,

---

for which information was available, 58 per cent in Asia, 94 per cent in the Americas, 97 per cent in Oceania, and 88 per cent in Europe (for seven countries only). Sex differentials in literacy were somewhat lower among those aged 15-19 years. Figures are for 1960-1970, calculated from *Demographic Yearbook, 1971* (United Nations publication, Sales No. E/F.72.XIII.1), table 18; and from *Demographic Yearbook, 1964* (United Nations publication, Sales No. E/F.65.XIII.1), table 33; *Demographic Yearbook, 1963* (United Nations publication, Sales No. E/F.64.XIII.1), tables 12 and 13.

<sup>7</sup> Females aged 5-14 were, on the average, approximately 79 per cent as likely as males the same age to be enrolled in school in countries of Africa for which information was available, 79 per cent in Asia, 100 per cent in the Americas and 98 per cent in Europe. But by ages 20-24, the ratio of female to male enrolment rates was only 15 per cent in Africa, 44 per cent in Asia, 65 per cent in the Americas and 57 per cent in Europe. Figures are for 1960-1970, calculated from *Demographic Yearbook, 1971*, table 20; *Demographic Yearbook, 1964*, table 36; *Demographic Yearbook, 1963*, table 15.

<sup>8</sup> Females in most countries of Latin America were, however, far less disadvantaged than those in most countries of Asia and Africa with similar rates of school enrolment for males.

<sup>9</sup> An average of approximately 20 per cent of women aged 15-19 were enrolled in school in countries of Africa reporting such information, 28 per cent in Asia, 29 per cent in the Americas and 32 per cent in Europe; but there were wide differences between countries and among socio-economic groups. See foot-note 11 for sources.

<sup>10</sup> In the United States of America, data from a national sample taken in 1965 of 1,600 high-school sessions, who were reinterviewed in 1971, showed that marriage and childbearing severely inhibited women from going to or staying in college, and women more so than men. Seventy-five per cent of married women with children at the time of the interview who had begun college dropped out, compared with 52 per cent of married men with children, 22 per cent of single women and 27 per cent of single men. A. J. Jaffe and Walter Adams, Bureau of Applied Social Research, New York; unpublished data.

delaying the first birth is likely to make little if any difference as to her educational opportunities although it may well have a significant effect on other aspects of her life.

11. In societies where women marry and bear children early and in which virtually all women marry, the obstacles to the woman's exercise of her right to an education may not be her lack of knowledge or means to plan and space children so much as the social, economic and cultural pressures that steer her into an early marriage in the first place. Parental control over the decision as to which of their children will attend school, the timing of their children's marriages and the choice of spouse may preclude a young woman from making an individual decision attaching a higher priority to education than to early motherhood.<sup>11</sup> On the other hand, the ability to delay marriage or a first birth does become salient as higher education for women becomes more generally accepted and valued.

12. Spacing pregnancies, limiting the number of births and ending childbirth earlier in the life cycle should also act independently to free women for formal schooling of various types, although the impact of these fertility variables on education is probably far weaker than the impact of postponing the onset of motherhood.<sup>12</sup> They may affect women's attendance at adult literacy classes, however.<sup>13</sup> In the long run, one would expect that as women increasingly delay, space and limit their birth, spending shorter and shorter periods of their lives in childbearing, their claim to equality in education will become all the more persistent. But education itself may be the very pre-condition necessary for motivated birth planning.

13. Is it possible to untangle the network of interacting variables into cause and effect? On one side, as has been indicated, early marriage itself or in combination with childbearing can "prevent" education by forcing or inducing women to discontinue their studies. Thus, where other structural and cultural conditions favour higher education for women, the effective postponement of marriage and/or births is often crucial to the exercise of their rights in this area. On the other side, education can "prevent" marriage and childbearing or postpone it beyond the average age of family formation as long as the woman stays in school.<sup>14</sup> From a
