

## UNMET NEED FOR FAMILY PLANNING

### DEFINITION AND COMPUTATION

Unmet need for family planning is defined as the percentage of women of reproductive age, either married or in a union, who have an unmet need for family planning. Women with unmet need are those who want to stop or delay childbearing but are not using any method of contraception.

$$\text{Unmet need for family planning} = \frac{\text{Women of reproductive age (15-49) who are married or in a union and who have an unmet need for family planning}}{\text{Total number of women of reproductive age (15-49) who are married or in a union}} \times 100$$

The standard definition of unmet need for family planning includes in the numerator women who are fecund and sexually active but are not using any method of contraception, and report not wanting any more children or wanting to delay the birth of their next child for at least two years. Included are:

- All pregnant women (married or in a union) whose pregnancies were unwanted or mistimed at the time of conception;
- All postpartum amenorrheic women (married or in a union) who are not using family planning and whose last birth was unwanted or mistimed;
- All fecund women (married or in a union) who are neither pregnant nor postpartum amenorrheic, and who either do not want any more children (want to limit family size), or who wish to postpone the birth of a child for at least two years or do not know when or if they want another child (want to space births), but are not using any contraceptive method.

Excluded from the numerator are infecund women. Women are assumed to be infecund if:

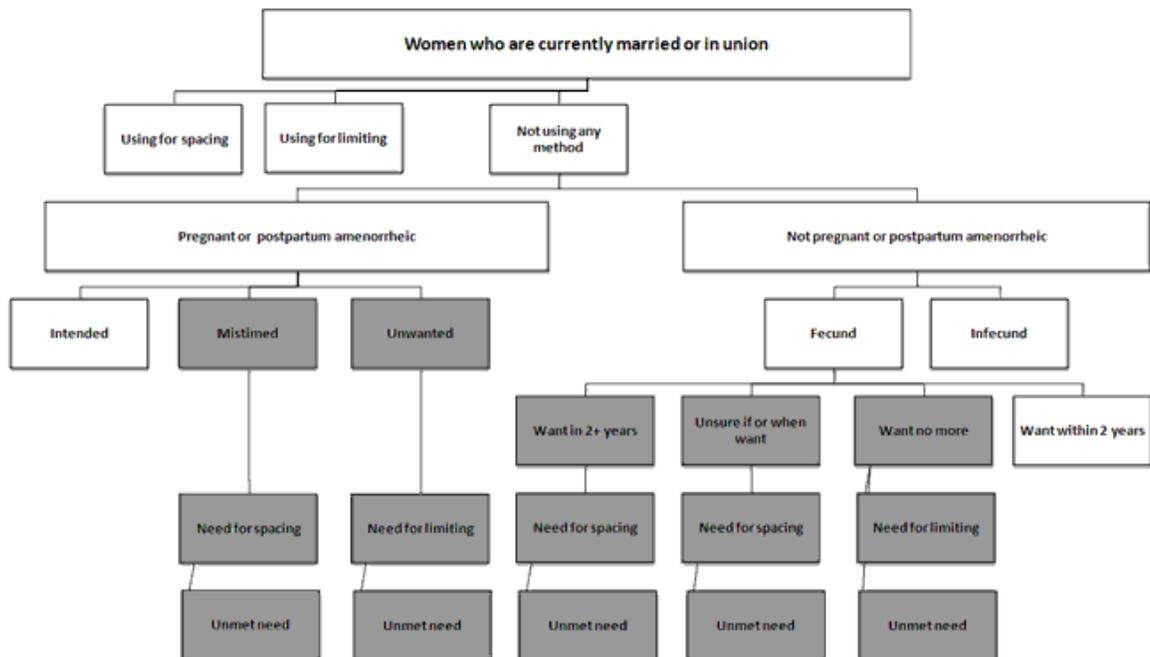

- They were first married five or more years ago, have not had a birth in the past five years, are not currently pregnant, and have never used any kind of contraceptive method; or
- They self-report that they are infecund, menopausal or have had a hysterectomy, never menstruated, or have been postpartum amenorrheic for 5 years or longer; or
- (for women who are not pregnant or in postpartum amenorrhea) their last menstrual period occurred more than six months prior to the survey.

Postpartum amenorrheic women are women who have not had a menstrual period since the birth of their last child and their last child was born in the period 0-23 months prior to the survey interview. If their period has not returned and their last child was born 24 months or more prior to the interview, women are considered fecund, unless they fall into

one of the infecund categories above. Note that in previous definitions of unmet need for family planning, women were classified as being postpartum amenorrheic if their period had not returned for up to 5 years after the birth of their last child.

Women who are married or in a union are assumed to be sexually active. If unmarried women are to be included in the calculation of unmet need, it is necessary to determine the timing of the most recent sexual activity. Unmarried women are considered currently at risk for pregnancy (and thus potentially in the numerator) if they have had intercourse in the month prior to the survey interview.

The diagram below indicates the procedure for the computation of the number of women of reproductive age, either married or in a union, who have an unmet need for family planning.

Further information on refinements in the operational definition over time, survey questions needed and statistical programs to calculate unmet need for family planning can be found on the following website: <http://measuredhs.com/Topics/Unmet-Need.cfm>

## SOURCES OF THE DATA

Information on unmet need for family planning is collected through household surveys that are internationally-coordinated, such as the Demographic and Health Surveys (DHS),

Multiple Indicator Cluster Surveys (MICS), Reproductive Health Surveys (RHS) and national surveys based on similar methodologies. These surveys tend to be undertaken every three to five years. Other survey programmes, like the Pan-Arab Project for Family Health (PAPFAM) and the European Fertility and Family Surveys (FFS) may be considered as well.

*World Fertility Report 2012* provides information on the source of each data point (usually denoted by an acronym). A description of each acronym is given in the table labelled "Sources". For surveys, the full name is provided in the field "Survey name".

## COMMENTS AND LIMITATIONS

Differences in the questions included in particular surveys may sometimes affect the estimates of unmet need for family planning and make comparability difficult over time or across countries. For example, some surveys do not gather all the information required to estimate infecundity in the same way. Differences in questions about contraceptive use, fertility desires and assessment of postpartum amenorrhea may also indirectly affect the measured level of unmet need for family planning.

Although the majority of estimates of unmet need for family planning follow the standard method of calculation, there can be differences in the precise definition or method of calculation of this indicator. For instance, some surveys do not include pregnant women with a mistimed or unwanted pregnancy in the number of women with unmet need for family planning. Notes are used to indicate any differences between the data presented in *World Fertility Report 2012* and the standard definition of unmet need for family planning given above.

Trends in unmet need for family planning in a particular population should be based on successive data points that were calculated in a comparable way. In designing and monitoring programmes aimed at reducing unmet need for family planning, this indicator should be interpreted in connection with other relevant national data, including qualitative and quantitative information regarding the reasons that women who are at risk of an undesired or mistimed pregnancy are not using family planning, and assessments of the availability and quality of family planning and other reproductive health services.

According to the standard definition of unmet need for family planning, women who are using a traditional method of contraception are not considered to have an unmet need for family planning. Because traditional methods can be considerably less effective than modern methods, additional analyses may be conducted to distinguish between women relying on traditional and modern methods in order to determine the unmet need for modern contraception.

### **Discrepancies between estimates presented in *World Fertility Report 2012* and other estimates**

Generally, there is no discrepancy between estimates presented in *World Fertility Report 2012* and unmet need for family planning published in national survey reports. However, some published national estimates of unmet need have been adjusted by the United Nations Population Division to improve comparability. Further, some published national estimates of unmet need are not included in *World Fertility Report 2012* because they were judged to depart too much from the core concept of unmet need employed here or because the estimation procedures were considered to produce results that were not comparable.

### **DATA COVERAGE AND REFERENCE YEARS FOR THE DATA REPORTED**

In *World Fertility Report 2012* data are provided, when available, for three reference dates: the closest years to 1970 (period 1965 to 1989), 1995 (period 1990 to 1999) and the most recent available year after 1999. Detailed distributions for each indicator by number of observations by reference dates are presented in the table labelled “Data availability”.

Data on unmet need for family planning are provided for 104 countries or areas of the world with a total population of 100,000 or more inhabitants in 2011. For 18 countries or areas, data are available for all three reference dates.
